# (54) INFORMATION PROCESSOR AND ITS METHOD, RECORDING MEDIUM, PROGRAM AND RECORDING MEDIUM

(57)Abstract:

PROBLEM TO BE SOLVED: To quickly and surely perform access to a desired position of an AV stream.

SOLUTION: The start point of a program and a picture in which the title of the program is displayed are respectively described in mark entry() and representative picture entry() in a clip constituting an AV stream.

#### **CLAIMS**

### [Claim(s)]

[Claim 1] While generating ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing said AV stream A generation means to generate PlayListMark which consists of marks which point to the image which the user specified as arbitration out of the playback section corresponding to PlayList which defines the combination of the predetermined section in said AV stream, The information processor characterized by having a record means to record on a record medium by using said ClipMark and PlayListMark as the table which became independent respectively.

[Claim 2] Said generation means is an information processor according to claim 1 characterized by generating said PlayList as a PlayList file while generating said ClipMark as a ClipMarkInformation file.

[Claim 3] Said PlayListMark is an information processor according to claim 1 characterized by being characterized by including further the mark which shows the Resume point when reproducing said PlayList.

[Claim 4] The information processor according to claim 1 characterized by referring to said mark which constitutes ClipMark of said AV stream corresponding to the playback section of said PlayList when reproducing said PlayList.

[Claim 5] Said mark of said PlayListMark is an information processor according to claim 1 characterized by including the identification information which shows the one playback section when it was specified on a presentation time stump and said AV stream data which constitute the salvage pathway of said PlayList.

[Claim 6] Said mark which constitutes said ClipMark, or said mark which constitutes said PlayListMark is an information processor according to claim 1 characterized by including the information which specifies the entry point of an elementary stream.

[Claim 7] Said mark of said PlayListMark is an information processor according to claim 1 characterized by including the information on the type which includes the start point of the favorite scene specified by a user, or the Resume point of PlayList at least.

[Claim 8] Said mark which constitutes said ClipMark, and said mark which constitutes said PlayListMark are an information processor according to claim 1 characterized by what is expressed with the address of the relative source packet corresponding to the entry point of said AV stream.

[Claim 9] Said mark which constitutes said ClipMark, and said mark which constitutes said PlayListMark are an information processor according to claim 8 characterized by what is expressed with the 2nd address which is the 1st address of the relative source packet corresponding to the entry point of said AV stream, and the address of the offset from said 1st address.

[Claim 10] Said 1st record means is an information processor according to

claim 1 characterized by what said mark which constitutes said ClipMark, and said type detected by said type detection means are made to correspond, and is recorded, including further a type detection means detect the type of said characteristic image detected on the occasion of record by said 1st record means.

[Claim 11] Said mark of said ClipMark is an information processor according to claim 1 characterized by including the scene as which the point changing [ scene ], the start point of commercials, the ending point of commercials, or the title was displayed.

[Claim 12] While generating ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing said AV stream Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in said AV stream The generation step which generates PlayListMark which consists of marks indicating the image which the user specified as arbitration, The information processing approach characterized by having the record control step which performs control at the time of recording on a record medium by using said ClipMark and PlayListMark as the table which became independent respectively.

[Claim 13] While generating ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing said AV stream Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in said AV stream The generation step which generates PlayListMark which consists of marks indicating the image which the user specified as arbitration, The record medium with which the program which the computer characterized by including the record control step which performs control at the time of recording on a record medium by using said ClipMark and PlayListMark as the table which became independent respectively can read is recorded.

[Claim 14] While generating ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing said AV stream Out of the playback section

corresponding to PlayList which defines the combination of the predetermined section in said AV stream The generation step which generates PlayListMark which consists of marks indicating the image which the user specified as arbitration, The program which makes a computer perform the record control step which performs control at the time of recording on a record medium by using said ClipMark and PlayListMark as the table which became independent respectively.

[Claim 15] The management information for managing said AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in said AV stream The read-out means which reads PlayListMark which consists of marks indicating the image which the user specified as arbitration, A presentation means to show said management information by which reading appearance was carried out with said read-out means, and the information by said PlayLisMark, A reference means to refer to said ClipMark corresponding to said PlayList the user instructed playback to be from said information shown by said presentation means, The information processor characterized by including a playback means to reproduce said AV stream from the location corresponding to said ClipMark, including said ClipMark referred to by said reference means.

[Claim 16] Said presentation means is an information processor according to claim 15 characterized by showing a user the list by the thumbnail image corresponding to said PlayLisMark.

[Claim 17] Said mark which constitutes said ClipMark, and said mark which constitutes said PlayListMark are an information processor according to claim 15 characterized by what is expressed with the address of the relative source packet corresponding to the entry point of said AV stream.

[Claim 18] Said mark which constitutes said ClipMark, and said mark which constitutes said PlayListMark are an information processor according to claim 17 characterized by what is expressed with the 2nd address which is the 1st address of the relative source packet corresponding to the entry point of said AV stream, and the address of the offset from said 1st address.

[Claim 19] Said mark of said ClipMark is an information processor according to claim 15 characterized by including the scene as which the point changing [scene], the start point of commercials, the ending point of commercials, or the title was displayed.

[Claim 20] The management information for managing said AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in said AV stream The read-out control step which controls read-out of PlayListMark which consists of marks indicating the image which the user specified as arbitration, The presentation step which presents said management information by which read-out was controlled by processing of said read-out control step, and the information by said PlayLisMark, The reference step which refers to said ClipMark corresponding to said PlayList the user instructed playback to be from said information shown by processing of said presentation step, The information processing approach characterized by including the playback control step which controls playback of said AV stream from the location corresponding to said ClipMark including said ClipMark referred to by processing of said reference step.

[Claim 21] The management information for managing said AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in said AV stream The read-out control step which controls read-out of PlayListMark which consists of marks indicating the image which the user specified as arbitration, The presentation step which presents said management information by which read-out was controlled by processing of said read-out control step, and the information by said PlayLisMark, The reference step which refers to said ClipMark corresponding to said PlayList the user instructed playback to be from said information shown by processing of said presentation step, The record medium with which the program which the computer characterized by including the playback control step which controls playback of said AV stream from the location corresponding to said ClipMark

including said ClipMark referred to by processing of said reference step can read is recorded.

[Claim 22] The management information for managing said AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in said AV stream The read-out control step which controls read-out of PlayListMark which consists of marks indicating the image which the user specified as arbitration, The presentation step which presents said management information by which read-out was controlled by processing of said read-out control step, and the information by said PlayLisMark, The reference step which refers to said ClipMark corresponding to said PlayList the user instructed playback to be from said information shown by processing of said presentation step, The program which makes a computer perform the playback control step which controls playback of said AV stream from the location corresponding to said ClipMark including said ClipMark referred to by processing of said reference step.

[Claim 23] The record medium characterized by what is recorded as a table on which PlayListMark which consists of marks indicating the image which the user specified as arbitration became independent respectively out of the playback section corresponding to PlayList which defines the combination of the management information for managing said AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, and the predetermined section in said AV stream.

#### DETAILED DESCRIPTION

[Detailed Description of the Invention] [0001]

[Field of the Invention] Especially this invention relates to a record medium at

the information processor which enabled it to access promptly an information processor and an approach, a record medium, a program, and a list about a record medium in the location of a request of AV stream and an approach, a record medium, a program, and a list.

[Description of the Prior Art] In recent years, record is possible and various kinds of optical disks are proposed as a dismountable disk mold medium from the record regenerative apparatus. The optical disk in which such record is possible is proposed as several G bytes of mass media, and its expectation as media which record AV (Audio Visual) signals, such as a video signal, is high.

[0003] There are a bit stream from which the recording apparatus itself carries out picture compression of the audio video signal of an analog input, and it makes it by MPEG-2 method as the source (supply source) of digital AV signal recorded on the optical disk in which this record is possible, a bit stream of the MPEG 2 method directly obtained from the electric wave of digital television broadcast, etc. Generally, an MPEG 2 transport stream is used in digital television broadcast. A transport stream is a stream which the transport packet followed, and, as for a transport packet, for example, an MPEG 2 video stream and an MPEG1 audio stream are packet-ized. The data length of one transport packet is 188 bytes. If AV program of the transport stream received by digital television broadcast is recorded on an optical disk as it is with a recording apparatus, it is possible to record without completely degrading the quality of video or an audio.

[0004]

[0002]

[Problem(s) to be Solved by the Invention] In order that a user may enable it to search the scene which is interested out of the transport stream currently recorded on the optical disk, for example, the point of a program pulling out the head etc., it is called for that random access playback can do a regenerative apparatus.

[0005] Generally, the stream of MPEG 2 video encodes I picture at intervals of about 0.5 seconds, and the other picture is encoded as P picture or a B picture. Therefore, when carrying out random access and carrying out video

recovery from the optical disk with which the stream of MPEG 2 video was recorded, I picture must be searched first.

[0006] However, when carrying out random access to the transport stream currently recorded on the optical disk and carrying out video recovery to it conventionally, it was difficult to search the start byte of I picture efficiently. that is, it was difficult to have to analyze the syntax of the video stream which carried out reading appearance, to have to search the start byte of I picture, and for the search of I picture to take time amount, and to perform quick random access playback of a response from the random byte position of the transport stream on an optical disk, to the input from a user.

[0007] This invention is made in view of such a situation, and enables it to perform promptly decision of the read-out location of the transport stream from a record medium, and decode initiation of a stream to directions of a random access rebirth of a user.

[8000]

[Means for Solving the Problem] While the 1st information processor of this invention generates ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing AV stream A generation means to generate PlayListMark which consists of marks which point to the image which the user specified as arbitration out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream, It is characterized by having a record means to record on a record medium by using ClipMark and PlayListMark as the table which became independent respectively.

[0009] Said generation means can generate PlayList as a PlayList file while generating ClipMark as a ClipMarkInformation file.

[0010] Said PlayListMark can include further the mark which shows the Resume point when reproducing PlayList.

[0011] When reproducing said PlayList, the mark which constitutes ClipMark of AV stream corresponding to the playback section of PlayList can be referred to.

[0012] The mark of said PlayListMark can contain the identification

information which shows the one playback section when it was specified on a presentation time stump and AV stream data which constitute the salvage pathway of PlayList.

[0013] The mark which constitutes said ClipMark, or the mark which constitutes PlayListMark can include the information which specifies the entry point of an elementary stream.

[0014] The mark of said PlayListMark can include the information on the type which includes the start point of the favorite scene specified by a user, or the Resume point of PlayList at least.

[0015] The mark which constitutes said ClipMark, and the mark which constitutes PlayListMark can be expressed with the address of the relative source packet corresponding to the entry point of AV stream.

[0016] The mark which constitutes said ClipMark, and the mark which constitutes PlayListMark can be expressed with the 2nd address which is the 1st address of the relative source packet corresponding to the entry point of AV stream, and the address of the offset from the 1st address.

[0017] Including further a type detection means to detect the type of the characteristic image detected on the occasion of record by said 1st record means, the 1st record means makes the mark which constitutes ClipMark, and the type detected by the type detection means correspond, and can be recorded.

[0018] The mark of said ClipMark can contain the scene as which the point changing [ scene ], the start point of commercials, the ending point of commercials, or the title was displayed.

[0019] While the 1st information processing approach of this invention generates ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing AV stream The generation step which generates PlayListMark which consists of marks which point to the image which the user specified as arbitration out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream, It is characterized by having the record control step which performs control at the time of recording on a record medium by using ClipMark and PlayListMark as the

table which became independent respectively.

[0020] While the program of the 1st record medium of this invention generates ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing AV stream. The generation step which generates PlayListMark which consists of marks which point to the image which the user specified as arbitration out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream, It is characterized by including the record control step which performs control at the time of recording on a record medium by using ClipMark and PlayListMark as the table which became independent respectively.

[0021] While the 1st program of this invention generates ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing AV stream The generation step which generates PlayListMark which consists of marks which point to the image which the user specified as arbitration out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream, A computer is made to perform the record control step which performs control at the time of recording on a record medium by using ClipMark and PlayListMark as the table which became independent respectively.

[0022] Management information for the 2nd information processor of this invention to manage AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, The read-out means which reads PlayListMark which consists of marks indicating the image which the user specified as arbitration out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream, A presentation means to show the information by the management information and PlayLisMark by which reading appearance was carried out with the read-out means, A reference means to refer to ClipMark corresponding to PlayList the user instructed playback to be from the information shown by the presentation means, It is characterized by including a playback means to reproduce AV stream from the location corresponding to

ClipMark, including ClipMark referred to by the reference means.

[0023] Said presentation means can show a user the list by the thumbnail image corresponding to PlayLisMark.

[0024] The mark which constitutes said ClipMark, and the mark which constitutes PlayListMark can be expressed with the address of the relative source packet corresponding to the entry point of AV stream.

[0025] The mark which constitutes said ClipMark, and the mark which constitutes PlayListMark can be expressed with the 2nd address which is the 1st address of the relative source packet corresponding to the entry point of AV stream, and the address of the offset from the 1st address.

[0026] The mark of said ClipMark can contain the scene as which the point changing [ scene ], the start point of commercials, the ending point of commercials, or the title was displayed.

[0027] Management information for the 2nd information processor of this invention to manage AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream The read-out control step which controls read-out of PlayListMark which consists of marks indicating the image which the user specified as arbitration, The presentation step which presents the information by the management information and PlayLisMark by which read-out was controlled by processing of a read-out control step, The reference step which refers to ClipMark corresponding to PlayList the user instructed playback to be from the information shown by processing of a presentation step, It is characterized by including the playback control step which controls playback of AV stream from the location corresponding to ClipMark including ClipMark referred to by processing of a reference step. [0028] Management information for the program of the 2nd record medium of this invention to manage AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream The read-out control step which controls read-out of PlayListMark which consists of marks indicating the

image which the user specified as arbitration, The presentation step which presents the information by the management information and PlayLisMark by which read-out was controlled by processing of a read-out control step, The reference step which refers to ClipMark corresponding to PlayList the user instructed playback to be from the information shown by processing of a presentation step, It is characterized by including the playback control step which controls playback of AV stream from the location corresponding to ClipMark including ClipMark referred to by processing of a reference step. [0029] Management information for the program of this invention to manage AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream The read-out control step which controls read-out of PlayListMark which consists of marks indicating the image which the user specified as arbitration, The presentation step which presents the information by the management information and PlayLisMark by which read-out was controlled by processing of a read-out control step, The reference step which refers to ClipMark corresponding to PlayList the user instructed playback to be from the information shown by processing of a presentation step, A computer is made to perform the playback control step which controls playback of AV stream from the location corresponding to ClipMark including ClipMark referred to by processing of a reference step. [0030] It is characterized by what is recorded as a table on which PlayListMark which consists of marks indicating the image which the user specified as arbitration became independent respectively out of the playback section corresponding to PlayList which defines the combination of the

management information for managing AV stream which contains in the 3rd record medium of this invention ClipMark which consists of marks indicating the characteristic image extracted from AV stream, and the predetermined section in AV stream.

[0031] It sets to a program at the 1st information processor of this invention and an approach, and a list. While generating ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing AV stream Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream PlayListMark which consists of marks indicating the image which the user specified as arbitration is generated, and it is recorded on a record medium as a table on which ClipMark and PlayListMark became independent respectively.

[0032] In the 2nd information processor of this invention and an approach, and a list, a program The management information for managing AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream Reading appearance of the PlayListMark which consists of marks indicating the image which the user specified as arbitration is carried out. The management information by which reading appearance was carried out, and the information by PlayLisMark are shown. From the shown information, ClipMark corresponding to PlayList the user instructed playback to be is referred to, and AV stream is reproduced from the location corresponding to ClipMark including ClipMark referred to.

[0033]
[Embodiment of the Invention] Below, the gestalt of operation of this invention

is explained with reference to a drawing. <u>Drawing 1</u> is drawing showing the example of an internal configuration of the record regenerative apparatus 1 which applied this invention. First, the configuration of the Records Department 2 which performs actuation which records the signal inputted from the outside on a record medium is explained. The record regenerative apparatus 1 is considered as the configuration which can input analog data or digital data and can be recorded.

[0034] The video signal of an analog is inputted into a terminal 11, and the audio signal of an analog is inputted into a terminal 12, respectively. The video signal inputted into the terminal 11 is outputted to the analysis section 14 and the AV encoder 15, respectively. The audio signal inputted into the terminal 12 is outputted to the analysis section 14 and the AV encoder 15. The analysis section 14 extracts the focus, such as a scene change, from the

inputted video signal and an audio signal.

[0035] The AV encoder 15 encodes the video signal and audio signal which were inputted, respectively, and outputs system information (S), such as a coding video stream (V), a coding audio stream (A), and AV synchronization, to a multiplexer 16.

[0036] A coding video stream is a video stream encoded for example, by MPEG(Moving Picture Expert Group) 2 method, and coding audio streams are the audio stream encoded for example, by MPEG1 method, an audio stream encoded by DORUBI AC3 method (trademark). A multiplexer 16 multiplexes the stream of the inputted video and an audio based on input system information, and outputs it to the multiplexing stream analysis section 18 and sow spa KETTAIZA 19 through a switch 17.

[0037] Multiplexing streams are for example, an MPEG 2 transport stream and an MPEG 2 program stream. Sow spa KETTAIZA 19 encodes the inputted multiplexing stream to AV stream which consists of source packets according to an application format of the record medium 100 on which the stream is made to record. Addition and modulation processing of an ECC sign are performed in the ECC (error correction) coding section 20 and the modulation section 21, and AV stream is outputted to the write-in section 22. The write-in section 22 writes AV stream file in a record medium 100 based on the control signal outputted from a control section 23 (it records). [0038] Transport streams, such as digital television broadcast inputted from a digital interface or a digital television tuner, are inputted into a terminal 13. They are the method which records those with two kind, and them on transparent at the recording method of a transport stream inputted into the terminal 13, and the method recorded after carrying out re-encoding for the objects, such as lowering a record bit rate. The directions information on a recording method is inputted into a control section 23 from the terminal 24 as a user interface.

[0039] When recording an input transport stream on transparent, the transport stream inputted into the terminal 13 is outputted to the multiplexing stream analysis section 18 and sow spa KETTAIZA 19 through a switch 17. Since processing until AV stream is recorded on the record medium 100 after this is

the same processing as the case where the above-mentioned input audio signal and above-mentioned video signal of an analog are encoded and recorded, the explanation is omitted.

[0040] When recording after re-encoding an input transport stream, the transport stream inputted into the terminal 13 is inputted into a demultiplexer 26. A demultiplexer 26 performs demultiplex processing to the inputted transport stream, and extracts a video stream (V), an audio stream (A), and system information (S).

[0041] A video stream is outputted to the AV decoder 27 among the streams (information) extracted by the demultiplexer 26, and an audio stream and system information are outputted to a multiplexer 16, respectively. The AV decoder 27 decodes the inputted video stream, and outputs the playback video signal to the AV encoder 15. The AV encoder 15 encodes an input video signal, and outputs a coding video stream (V) to a multiplexer 16. [0042] On the other hand, based on input system information, the audio stream which was outputted from the demultiplexer 26 and inputted into the multiplexer 16, system information, and the video stream outputted from the AV encoder 15 are multiplexed, and is outputted to the multiplexing stream analysis section 18 and source packet TAIZA 19 through a switch 17 as a multiplexing stream. Since processing until AV stream is recorded on the record medium 100 after this is the same processing as the case where the above-mentioned input audio signal and above-mentioned video signal of an analog are encoded and recorded, the explanation is omitted.

[0043] The record regenerative apparatus 1 of the gestalt of this operation also records the application database information that the file is explained while recording the file of AV stream on a record medium 100. Application database information is created by the control section 23. The input to a control section 23 is the description information on the dynamic image from the analysis section 14, the description information on AV stream from the multiplexing stream analysis section 18, and the directions information from a user that it is inputted from a terminal 24.

[0044] The description information on the dynamic image supplied from the analysis section 14 is generated by the analysis section 14 when the AV

encoder 15 encodes a video signal. The analysis section 14 analyzes the content of an input video signal and the audio signal, and generates the information related to the characteristic image in an input dynamic-image signal (clip mark). This is the directions information on the image of the characteristic points marking [ clip ], such as start point [ of the program in an input video signal ], and changing [ scene ] point and starting point [ of CM commercials ] - and a point, a title, and a telop, and the thumbnail of the image is also contained in it. Furthermore, the stereo of an audio signal, and the switching point of a monophonic recording and the information on the silent section etc. are also included.

[0045] The directions information on these images is inputted into a multiplexer 16 through a control section 23. A multiplexer 16 returns the information for specifying the coding picture on AV stream to a control section 23, when multiplexing the coding picture specified as a clip mark from a control section 23. Specifically, this information is the address information on PTS (presentation time stump) of a picture, or AV stream of that coding picture. A control section 23 associates and memorizes the information for specifying the class and its coding picture of a characteristic image on AV stream.

[0046] The description information on AV stream from the multiplexing stream analysis section 18 is the information related to the encoded information of AV stream recorded, and is generated by the analysis section 18. For example, the changing point information on the time stump of I picture in AV stream, address information, the break point information on a system time clock, the coding parameter of AV stream, and the coding parameter in AV stream etc. is included. Moreover, when recording the transport stream inputted from a terminal 13 on transparent, the multiplexing stream analysis section 18 detects the image of the above-mentioned clip mark out of an input transport stream, and generates the information for specifying the picture specified by the class and clip mark.

[0047] The directions information of the user from a terminal 24 is the character alphabetic character explaining the assignment information on the playback section specified by the user in AV stream, and the content of the

playback section, the bookmark which a user sets to a favorite scene, the information on a resume point, etc.

[0048] A control section 23 creates the management information (info.dvr) of the database (Clip) of AV stream, the database of what (PlayList) carried out grouping of the playback section (PlayItem) of AV stream, and the content of record of a record medium 100, and the information on a thumbnail image based on the above-mentioned input. Like AV stream, the application database information which consists of such information is processed in the ECC coding section 20 and the modulation section 21, and is inputted into the write-in section 22. The write-in section 22 records a database file on a record medium 100 based on the control signal outputted from a control section 23. [0049] The detail about the application database information mentioned above is mentioned later.

[0050] Thus, when application database information is reproduced by the playback section 3 with AV stream file (file of image data and voice data) recorded on the record medium 100, a control section 23 directs to read application database information from a record medium 100 to the read-out section 28 first. And the read-out section 28 reads application database information from a record medium 100, and the application database information is inputted into a control section 23 through a recovery and error correction processing of the recovery section 29 and the ECC decode section 30.

[0051] A control section 23 outputs the list of PlayList currently recorded on the record medium 100 to the user interface of a terminal 24 based on application database information. A user chooses PlayList to reproduce from the list of PlayList, and the information about PlayList which had playback specified is inputted into a control section 23. A control section 23 directs read-out of AV stream file required for playback of the PlayList in the read-out section 28. The read-out section 28 reads AV stream which corresponds from a record medium 100 according to the directions, and outputs it to the recovery section 29. It gets over by performing predetermined processing, and AV stream inputted into the recovery section 29 is further outputted source DEPAKETTAIZA 31 through processing of the ECC decode section 30.

[0052] Reading appearance of source DEPAKETTAIZA 31 is carried out from a record medium 100, and it changes AV stream of an application format to which predetermined processing was performed into the stream which can process a demultiplexer 26. A demultiplexer 26 outputs system information (S), such as a video stream (V) which constitutes the playback section (PlayItem) of AV stream specified by the control section 23, an audio stream (A), and AV synchronization, to the AV decoder 27. The AV decoder 27 decodes a video stream and an audio stream, and outputs a playback video signal and a playback audio signal from the terminal 32 and terminal 33 which correspond, respectively.

[0053] Moreover, when the information which directs random access playback and special playback is inputted from the terminal 24 as a user interface, based on the content of the database (Clip) of AV stream, a control section 23 determines the read-out location of AV stream from a storage 100, and directs read-out of the AV stream in the read-out section 28. For example, when reproducing PlayList chosen by the user from predetermined time of day, as a control section 23 reads the data with the time stump nearest to the specified time of day from I picture, it is read, and it is directed in the section 28. [0054] moreover, out of the point of the program currently stored in ClipMark in Clip Information pulling out the head, or the point changing [scene] When a clip mark with a user is chosen (for example, this actuation) The thumbnail image list of the point of a program pulling out the head or points changing [ scene ] currently stored in ClipMark is displayed on a user interface. Based on the content of Clip Information, a user determines the read-out location of AV stream from a record medium 100, reads read-out of the AV stream, and directs the control section 23 performed by choosing a certain image from the inside to the section 28. That is, it reads so that the data from I picture in the address nearest to the address on AV stream in which the image which the user chose is stored may be read, and it directs to the section 28. AV data which the read-out section 28 reads data from the specified address, and the data by which reading appearance was carried out are inputted into a demultiplexer 26 through processing of the recovery section 29, the ECC decode section 30, and source DEPAKETTAIZA 31, are decoded by the AV

decoder 27, and are shown in the address of the picture of a marking point are reproduced.

[0055] Moreover, when high-speed playback (Fast-forward playback) is directed by the user, as sequential continuation is carried out and a control section 23 reads I-picture data in AV stream based on the database (Clip) of AV stream, it is read, and it is directed in the section 28.

[0056] The read-out section 28 reads the data of AV stream from the specified random access point, and the data by which reading appearance was carried out are reproduced through processing of latter each part.

[0057] Next, a user explains the case where AV stream currently recorded on the record medium 100 is edited. When a user wants to specify the playback section of AV stream currently recorded on the record medium 100, and to create new salvage pathway, For example, from the song program of Program A, reproduce Singer's A part and it continues after that. The information on the start point (Inn point) of the playback section and an ending point (out point) is inputted into a control section 23 from the terminal 24 as a user interface to create the salvage pathway of wanting to reproduce the part of the singer A of the song program of Program B. A control section 23 creates the database of what (PlayList) carried out grouping of the playback section (PlayItem) of AV stream.

[0058] When a user wants to eliminate a part of AV stream currently recorded on the record medium 100, the information on the Inn point of the elimination section and an out point is inputted into a control section 23 from the terminal 24 as a user interface. A control section 23 changes the database of PlayList so that only required AV stream part may be referred to. Moreover, it directs in the write-in section 22 so that the unnecessary stream part of AV stream may be eliminated.

[0059] It is the case where a user wants to specify the playback section of AV stream currently recorded on the record medium 100, and to create new salvage pathway, and the case where he wants to connect each playback section seamlessly is explained. In such a case, a control section 23 creates the database of what (PlayList) carried out grouping of the playback section (PlayItem) of AV stream, and performs near a node partial re-encoding and

re-multiplexing of the playback section of a video stream further.

[0060] First, the information on the picture of the Inn point of the playback section and the information on the picture of an out point are inputted into a control section 23 from a terminal 24. A control section 23 directs read-out of data required in order to reproduce the Inn point side picture and the picture by the side of an out point in the read-out section 28. And the read-out section 28 reads data from a record medium 100, and the data is outputted to a demultiplexer 26 through the recovery section 29, the ECC decode section 30, and source DEPAKETTAIZA 31.

[0061] A control section 23 analyzes the data inputted into the demultiplexer 26, determines a re-multiplex system as the re-encoding approach (modification of picture\_coding\_type, assignment of the re-encoded amount of coding bits) of a video stream, and supplies the method to the AV encoder 15 and a multiplexer 16.

[0062] Next, a demultiplexer 26 divides the inputted stream into a video stream (V), an audio stream (A), and system information (S). A video stream has the data inputted into the AV decoder 27, and data inputted into a multiplexer 16. It is data required in order to re-encode the former data, and this is decoded by the AV decoder 27, and the decoded picture is re-encoded with the AV encoder 15, and is made into a video stream. The latter data are data copied from the stream of an original copy without carrying out re-encoding. About an audio stream and system information, it is directly inputted into a multiplexer 16.

[0063] Based on the information inputted from the control section 23, a multiplexer 16 multiplexes an input stream and outputs a multiplexing stream. A multiplexing stream is processed in the ECC coding section 20 and the modulation section 21, and is inputted into the write-in section 22. The write-in section 22 records AV stream on a record medium 100 based on the control signal supplied from a control section 23.

[0064] Explanation about actuation of the playback and edit based on application database information and its information is given to below.

Drawing 2 is drawing explaining the structure of an application format. An application format has two layers, PlayList and Clip, for management of AV

stream. Volume Information carries out management of all Clip(s) and PlayList(s) in a disk. Here, the pair of one AV stream and its attached information is considered to be one object, and it is called Clip. AV stream file calls Clip AV stream file, and the attached information is called Clip Information file.

[0065] One Clip AV stream file stores the data which have arranged the MPEG 2 transport stream in the structure in which it is specified by application format. Generally, although a file is treated as a sequence of bytes, the contents of Clip AV stream file are developed on a time-axis, and the entry point in Clip (I picture) is mainly specified in a hourly base. When the time stump of the access point to predetermined Clip is given, Clip Information file is useful in order to find the address information which should start read-out of data in Clip AV stream file.

[0066] PlayList is explained with reference to <u>drawing 3</u>. PlayList chooses from Clip(s) the playback section which a user wants to see, and it is prepared in order to enable it to edit it simply. One PlayList is the meeting of the playback section in Clip. The one playback section in predetermined Clip is called PlayItem, and it is expressed with the pair of the Inn point on a time-axis (IN), and an out point (OUT). Therefore, PlayList is constituted when two or more PlayItem(s) gather.

[0067] There are two types of PlayList(s). One is Real PlayList and another is Virtual PlayList. Real PlayList is sharing the stream part of Clip which it is referring to. That is, when Real PlayList occupies in a disk the data volume equivalent to the stream part of Clip which is referring to it and Real PlayList is eliminated, data are eliminated also for the stream part of Clip which it is referring to.

[0068] Virtual PlayList is not sharing the data of Clip. Therefore, even if Virtual PlayList is changed or eliminated, by the content of Clip, change does not arise at all.

[0069] Next, edit of Real PlayList is explained. <u>Drawing 4</u> (A) is drawing about the creation (create: creation) of Real PlayList, and when AV stream is recorded as new Clip, it is actuation in which Real PlayList which refers to the whole Clip is newly created.

[0070] <u>Drawing 4</u> (B) is drawing about the divide (divide: division) of Real PlayList, and is actuation in which Real PlayList is divided at a point [ \*\*\*\* ] and divided into two Real PlayList. when two programs are managed in one clip managed by one PlayList, a user wants to do the actuation of this division again registration (record) as each program -- like -- it is sometimes carried out. There is nothing for which the content of Clip is changed by this actuation (the Clip itself is divided).

[0071] <u>Drawing 4</u> (C) is drawing about the combined harvester and thresher (combine: association) of Real PlayList, and is actuation which combines two Real PlayList and is set to one new Real PlayList. a user wants, as for the actuation of this association, to reregister two programs as one program -- like -- it is sometimes carried out. There is nothing for which Clip is changed by this actuation (the Clip itself is set to one).

[0072] <u>Drawing 5</u> (A) is drawing about deletion (delete: deletion) of whole Real PlayList, and when actuation which eliminates whole predetermined Real PlayList is carried out, the stream part to which Clip which deleted Real PlayList refers to corresponds is also deleted.

[0073] <u>Drawing 5</u> (B) is drawing about partial deletion of Real PlayList, and when a part [ \*\*\*\* / Real PlayList ] is deleted, it is changed so that corresponding PlayItem may refer to only the stream part of required Clip. And the stream part to which Clip corresponds is deleted.

[0074] <u>Drawing 5</u> (C) is drawing about minimization (Minimize: minimization) of Real PlayList, and is actuation of referring to only the stream part of Clip required for Virtual PlayList for PlayItem corresponding to Real PlayList. Virtual PlayList The stream part to which it takes and unnecessary Clip corresponds is deleted.

[0075] Real PlayList is changed by actuation which was mentioned above, when the stream part of Clip which the Real PlayList refers to is deleted, Virtual PlayList which is using the deleted Clip may exist, and a problem may arise by deleted Clip in the Virtual PlayList.

[0076] As opposed to actuation of [ so that such a thing may not arise ] deletion to a user "If Virtual PlayList which is referring to the stream part of Clip which the Real PlayList is referring to exists and the Real PlayList is

eliminated although the Virtual PlayList will also be eliminated, is still it good? processing of the deletion with directions of a user after urging a check (warning) by displaying the message " etc. -- activation -- or it cancels. Or actuation of minimization is made to be performed instead of deleting Virtual PlayList to Real PlayList.

[0077] Next, the actuation to Virtual PlayList is explained. The content of Clip is not changed even if actuation is performed to Virtual PlayList. <u>Drawing 6</u> is an assemble (Assemble). Edit (IN-OUT edit) It is related drawing and is actuation of making PlayItem of the playback section for which it asked when the user wanted to see, and creating Virtual PlayList. The seamless connection between PlayItem(s) is supported by the application format (aftermentioned).

[0078] As shown in <u>drawing 6</u> (A), two Real PlayList 1 and 2, When Clip 1 and 2 corresponding to each RealPlayList exists A user directs the predetermined section in Real PlayList1 (section-layItem1 to In1 thru/or Out1) as the playback section, and as the section reproduced continuously When the predetermined section in Real PlayList2 (section-layItem2 to In2 thru/or Out2) is directed as the playback section, As shown in <u>drawing 6</u> (B), one Virtual PlayList which consists of PlayItem1 and PlayItem2 is created.

[0079] Next, Virtual PlayList A reorganization collection (Re-editing) is explained. A reorganization collection has insertion (insert) of modification of the Inn point in Virtual PlayList, and an out point, and new PlayItem to Virtual PlayList, an addition (append), deletion of PlayItem in Virtual PlayList, etc. Moreover, Virtual PlayList itself can also be deleted.

[0080] <u>Drawing 7</u> is drawing about postrecording (Audio dubbing (post recording)) of the audio to Virtual PlayList, and is actuation which registers postrecording of the audio to Virtual PlayList as subpass. Postrecording of this audio is supported by the application format. An additional audio stream is added to AV stream of the main path of Virtual PlayList as subpass.

[0081] As actuation common to Real PlayList and Virtual PlayList, there is modification (Moving) of the playback sequence of PlayList as shown in

drawing 8. This actuation is modification of the playback sequence of PlayList in the inside of a disk (volume), and is supported by Table Of PlayList (with

reference to <u>drawing 20</u> etc., it mentions later) defined in an application format. As [ change / by this actuation / the content of Clip ]

[0082] Next, a mark (Mark) is explained. The mark is prepared in order to specify the highlights in Clip and PlayList, and characteristic time amount, as shown in drawing 9. The mark added to Clip is called ClipMark (clip mark). Specify the characteristic scene resulting from the content of the AV stream, for example, ClipMark is a head broth point, a point changing [ scene ], etc. of a program. ClipMark is generated by the analysis section 14 of drawing 1. When reproducing PlayList, it can be used with reference to the mark of Clip which the PlayList refers to.

[0083] The mark added to PlayList is called PlayListMark (play list mark). Are mainly set by the user, for example, PlayListMark(s) are a bookmark, a resume point, etc. Setting a mark to Clip or PlayList is performed by adding the time stump in which the time of day of a mark is shown to a mark list. Moreover, deleting a mark is removing the time stump of the mark out of a mark list. Therefore, as for AV stream, a change of what is not made by setting out or deletion of a mark, either.

[0084] You may make it specify the picture which ClipMark refers to with the address base in the inside of AV stream as another format of ClipMark. Setting a mark to Clip is performed by adding the information on the address base which shows the picture of a marking point to a mark list. Moreover, deleting a mark is removing the information on the address base which shows the picture of the marking point out of a mark list. Therefore, as for AV stream, a change of what is not made by setting out or deletion of a mark, either. [0085] Next, a thumbnail is explained. A thumbnail is a still picture added to Volume, PlayList, and Clip. There are two classes of thumbnails and one is a thumbnail as representation drawing showing the content. This is used in the menu screen for choosing the thing a user mainly wants to operate and look at cursor (un-illustrating) etc. Another is an image showing the scene which the mark has pointed out.

[0086] Volume and each Playlist need to enable it to have representation drawing. The representation drawing of Volume assumes being used when displaying the still picture showing the content of the disk first, when a disk (a

record medium 100 presupposes that it is a disk-like thing, and is suitably described to be a disk a record medium 100 and the following) is set to the predetermined location of the record regenerative apparatus 1. The representation drawing of Playlist assumes being used as a still picture for expressing the content of Playlist in the menu screen which chooses Playlist. [0087] Although it is possible as representation drawing of Playlist to make the image of the beginning of Playlist into a thumbnail (representation drawing), it is not not necessarily the image optimal when the image of the head of the playback time of day 0 expresses the content. Then, a user enables it to set up the image of arbitration as a thumbnail of Playlist. Two kinds of thumbnails, the thumbnail as representation drawing which expresses Volume above, and the thumbnail as representation drawing showing PlayList, are called a menu thumbnail. Since a menu thumbnail is displayed frequently, reading appearance of it needs to be carried out to a high speed from a disk. For this reason, it is efficient to store all menu thumbnails in one file. It is not necessary to be necessarily the picture extracted from the animation in volume, and as shown in drawing 10, a menu thumbnail may be taken from a personal computer or a digital still camera, and a \*\*\*\*\*\*\*\* image is sufficient as it.

[0088] It can be necessary to strike two or more marks, and in order to know the content of the mark location, it is necessary to enable it to see the image of a marking point easily to Clip and Playlist on the other hand. The picture showing such a marking point is called a mark thumbnail (Mark Thumbnails). Therefore, the image which becomes the origin of a mark thumbnail becomes main [ what extracted the image of a marking point ] from the image captured from the outside.

[0089] <u>Drawing 11</u> is the mark attached to PlayList, and drawing showing the relation of the mark thumbnail, and <u>drawing 12</u> is the mark attached to Clip, and drawing showing the relation of the mark thumbnail. Since a mark thumbnail is used by the sub menu etc. when the detail of Playlist is expressed unlike a menu thumbnail, what reading appearance is carried out in the short access time is not required. Therefore, it does not become a problem, even if it takes time amount somewhat because the record

regenerative apparatus 1 reads an aperture and a part of its file for a file whenever a thumbnail is needed.

[0090] Moreover, in order to reduce the number of files which exists in volume, all mark thumbnails are good to store in one file. Although Playlist can have one-menu thumbnail and two or more mark thumbnails, since Clip does not have the need that a direct user chooses (it usually specifies via Playlist), it does not need to prepare a menu thumbnail.

[0091] Drawing 13 is drawing having shown the relation of the menu thumbnail at the time of taking having mentioned above into consideration, a mark thumbnail, PlayList, and Clip. The menu thumbnail prepared in the menu thumbnail file for every PlayList is filed. The volume thumbnail representing the content of the data currently recorded on the disk is contained in the menu thumbnail file. The thumbnail by which the mark thumbnail file was created for every Clip with every PlayList is filed.

[0092] Next, CPI (Characteristic Point Information) is explained. CPI is data contained in a Clip information file, and when the time stump of the access point to Clip is given, it is mainly used in order to find the data address which should start read-out of data in Clip AV stream file. Two kinds of CPI(s) are used with the gestalt of this operation. One is EP\_map and another is TU\_map.

[0093] EP\_map is the list of entry point (EP) data, and it is extracted from an elementary stream and a transport stream. This has the address information for finding the location of the entry point which should start decoding in AV stream. One EP data consists of pairs of the data address in a presentation time stump (PTS) and AV stream of the access unit corresponding to the PTS. [0094] EP\_map is mainly used for two objects. It is used in order to find the data address in AV stream of the access unit referred to [1st] with a presentation time stump in PlayList. It is used for the 2nd for first forward playback or first reverse playback. When the record regenerative apparatus 1 records an input AV stream and the syntax of the stream can be analyzed, EP\_map is created and it is recorded on a disk.

[0095] TU\_map has the list of the time unit (TU) data based on the arrival time of the transport packet inputted through a digital interface. This gives the

regenerative apparatus 1 reads an aperture and a part of its file for a file whenever a thumbnail is needed.

[0090] Moreover, in order to reduce the number of files which exists in volume, all mark thumbnails are good to store in one file. Although Playlist can have one menu thumbnail and two or more mark thumbnails, since Clip does not have the need that a direct user chooses (it usually specifies via Playlist), it does not need to prepare a menu thumbnail.

[0091] <u>Drawing 13</u> is drawing having shown the relation of the menu thumbnail at the time of taking having mentioned above into consideration, a mark thumbnail, PlayList, and Clip. The menu thumbnail prepared in the menu thumbnail file for every PlayList is filed. The volume thumbnail representing the content of the data currently recorded on the disk is contained in the menu thumbnail file. The thumbnail by which the mark thumbnail file was created for every Clip with every PlayList is filed.

[0092] Next, CPI (Characteristic Point Information) is explained. CPI is data contained in a Clip information file, and when the time stump of the access point to Clip is given, it is mainly used in order to find the data address which should start read-out of data in Clip AV stream file. Two kinds of CPI(s) are used with the gestalt of this operation. One is EP\_map and another is TU\_map.

[0093] EP\_map is the list of entry point (EP) data, and it is extracted from an elementary stream and a transport stream. This has the address information for finding the location of the entry point which should start decoding in AV stream. One EP data consists of pairs of the data address in a presentation time stump (PTS) and AV stream of the access unit corresponding to the PTS. [0094] EP\_map is mainly used for two objects. It is used in order to find the data address in AV stream of the access unit referred to [1st] with a presentation time stump in PlayList. It is used for the 2nd for first forward playback or first reverse playback. When the record regenerative apparatus 1 records an input AV stream and the syntax of the stream can be analyzed, EP\_map is created and it is recorded on a disk.

[0095] TU\_map has the list of the time unit (TU) data based on the arrival time of the transport packet inputted through a digital interface. This gives the

relation between the time amount of the arrival time base, and the data address in AV stream. When the record regenerative apparatus 1 records an input AV stream and the syntax of the stream cannot be analyzed, TU\_map is created and it is recorded on a disk.

[0096] STCInfo stores the break point information on STC in AV stream file which is storing the MPEG 2 transport stream. Temporarily, when AV stream has the break point of STC, PTS of the same value may appear in the AV stream file. Therefore, when pointing out the predetermined time of day on AV stream with the PTS base, just PTS of an access point is inadequate in order to specify the point.

[0097] Furthermore, the index of the STC section [ \*\*\*\* ] containing the PTS is required. In this format, STC-sequence, a call, and its index are described to be STC-sequence-id for the STC section [ \*\*\*\* ]. The information on STC-sequence is defined by STCInfo of Clip Information file. STC-sequence-id is an option in AV stream file which uses it by AV stream file with EP\_map, and has TU\_map.

[0098] A program is the meeting of an elementary stream and shares only one system time base for synchronous playback of these streams. What the content of the AV stream understands in advance of decoding of AV stream for a regenerative apparatus is useful. For example, they are information, such as a value of PID of the transport packet which transmits the elementary stream of video or an audio, video, and a component class of audio, (for example, audio streams of the video of HDTV, and MPEG-2 AAC etc.). [0099] This information is useful although the menu screen which explains to a user the content of PlayList which refers to AV stream is created, and it is useful in order to set AV decoder of a regenerative apparatus, and the initial state of a demultiplexer in advance of decoding of AV stream. For this reason, Clip Information file has ProgramInfo for explaining the content of the program. [0100] As for AV stream file which is storing the MPEG 2 transport stream, the content of a program may change in a file. For example, it is that PID of the transport packet which transmits a video elementary stream changes, or the component class of video stream changes from SDTV to HDTV etc. [0101] ProgramInfo stores the information on the changing point of the

content of a program in the inside of AV stream file. In AV stream file, the content of a program defined in this format calls the fixed section Program-sequence. Program-sequence is an option in AV stream file which uses it by AV stream file with EP\_map, and has TU\_map.

[0102] The gestalt of this operation defines the stream format (SESF) of self encoding. SESF is used when encoding to an MPEG 2 transport stream, after decoding the object which encodes an analog input signal, and a digital input signal (for example, DV).

[0103] SESF defines a coding limit of the elementary stream about an MPEG-2 transport stream and AV stream. When the record regenerative apparatus 1 encodes and records a SESF stream, EP\_map is created and it is recorded on a disk.

[0104] Either of the methods shown below is used and the stream of digital broadcasting is recorded on a record medium 100. First, transformer coding of the stream of digital broadcasting is carried out at a SESF stream. In this case, the recorded stream must be based on SESF. In this case, EP\_map must be created and it must be recorded on a disk.

[0105] Or transformer coding is carried out at a new elementary stream, and the elementary stream which constitutes a digital-broadcasting stream is remultiplexed to the new transport stream based on the stream format which the normalization organization of the digital-broadcasting stream defines. In this case, EP\_map must be created and it must be recorded on a disk.

[0106] For example, an input stream is an MPEG-2 transport stream of ISDB (specification name of digital BS broadcast of Japan) conformity, and suppose that it contains a HDTV video stream and a MPEG AAC audio stream.

Transformer coding of the HDTV video stream is carried out at a SDTV video stream, and the SDTV video stream and AAC audio stream of an original copy are re-multiplexed to TS. Both the transport streams recorded as a SDTV stream must be based on an ISDB format.

[0107] The stream of digital broadcasting is the case (it records without changing any input transport streams) where an input transport stream is recorded on transparent as other methods at the time of being recorded on a record medium 100, and EP\_map is then created and it is recorded on a disk.

[0108] Or it is the case (it records without changing any input transport streams) where an input transport stream is recorded on transparent, and TU\_map is then created and it is recorded on a disk.

[0109] Next, a directory and a file are explained. Hereafter, the record regenerative apparatus 1 is suitably described to be DVR (Digital Video Recording). Drawing 14 is drawing showing an example of the directory structure on a disk. Directories required on the disk of DVR are a root directory including a "DVR" directory, a "PLAYLIST" directory, a "CLIPINF" directory, and a "DVR" directory including an "M2TS" directory and "DATA" directory, as shown in drawing 14. Although directories other than these may be made to be created under a root directory, they presuppose that it is ignored in an application format of the gestalt of this operation.

[0110] All the files and directories that are specified by DVR application format in the bottom of a "DVR" directory are stored. A "DVR" directory includes four directories. On the bottom of a "PLAYLIST" directory, the database file of Real PlayList and Virtual PlayList is put. This directory exists, even if one does not have PlayList.

[0111] The database of Clip is put on the bottom of a "CLIPINF" directory. This directory also exists, even if Clip does not have one. AV stream file is put on the bottom of an "M2TS" directory. This directory exists, even if one does not have AV stream file. As for the "DATA" directory, the file of data broadcasting, such as digital TV broadcast, is stored.

[0112] A "DVR" directory stores the file shown below. It is made under a "info.dvr" file and a DVR directory, and the overall information on an application layer is stored. Only one info.dvr must be in the bottom of a DVR directory. A file name presupposes that it is fixed to info.dvr. A "menu.thmb" file stores the information relevant to a menu thumbnail image. Zero or one menu thumbnail must be in the bottom of a DVR directory. A file name presupposes that it is fixed to memu.thmb. When one does not have a menu thumbnail image, this file does not need to exist.

[0113] A "mark.thmb" file stores the information relevant to a mark thumbnail image. Zero or one mark thumbnail must be in the bottom of a DVR directory. A file name presupposes that it is fixed to mark.thmb. When one does not

have a menu thumbnail image, this file does not need to exist.

[0114] A "PLAYLIST" directory stores two kinds of PlayList files, and they are Real PlayList and Virtual PlayList. "xxxxx.rpls" A file stores the information relevant to one Real PlayList. One file is made for every Real PlayList. A file name is "xxxxx.rpls." Here, "xxxxx" is a figure to five 0 thru/or 9. A file extension child presupposes that it must be "rpls".

[0115] A "yyyyy.vpls" file stores the information relevant to one Virtual PlayList. One file is made for every Virtual PlayList. A file name is "yyyyy.vpls." Here, "yyyyy" is a figure to five 0 thru/or 9. A file extension child presupposes that it must be "vpls".

[0116] A "CLIPINF" directory stores one file corresponding to each AV stream file. "zzzzz.clpi" A file is Clip Information file corresponding to one AV stream file (Clip AV stream file or Bridge-Clip AV stream file). A file name is "zzzzz.clpi" and "zzzzz" is a figure to five 0 thru/or 9. A file extension child presupposes that it must be "clpi".

[0117] An "M2TS" directory stores the file of AV stream. A "zzzzz.m2ts" file is an AV stream file treated by the DVR system. This is Clip AV stream file or Bridge-Clip AV stream. A file name is "zzzzz.m2ts" and "zzzzz" is a figure to five 0 thru/or 9. A file extension child presupposes that it must be "m2ts." [0118] The "DATA" directory stores the data transmitted from data broadcasting, and data are for example, XML file, an MHEG file, etc. [0119] Next, the syntax and semantics of each directory (file) are explained. First, a "info.dvr" file is explained. Drawing 15 is drawing showing the syntax of a "info.dvr" file. A "info.dvr" file consists of three objects and they are DVRVolume(), TableOfPlayLists(), and MakersPrivateData(). [0120] TableOfPlayLists\_Start\_address shows the start address of TableOfPlayList() for explaining the syntax of info.dvr shown in drawing 15 by making the relative byte count from the cutting tool of the head of an info.dvr file into a unit. A relative byte count is counted from zero.

[0121] MakersPrivateData\_Start\_address shows the start address of MakersPrivateData() by making the relative byte count from the cutting tool of the head of an info.dvr file into a unit. A relative byte count is counted from zero. padding\_word (padding WORD) is inserted according to the syntax of

info.dvr. N1 and N2 are the positive integers of zero or arbitration. You may make it each padding WORD take any value.

[0122] DVRVolume() stores the information which describes the content of volume (disk). <u>Drawing 16</u> is drawing showing the syntax of DVRVolume(). version\_number shows four character alphabetic characters which show the version number of this DVRVolume() for explaining the syntax of DVR Volume() shown in <u>drawing 16</u> . version\_number is encoded with "0045" according to ISO 646.

[0123] length is expressed with the 32-bit unsigned integer which shows the byte count of DVRVolume() from immediately after this length field to the last of DVRVolume().

[0124] ResumeVolume() has memorized the file name of Real PlayList reproduced at the end in volume, or Virtual PlayList. However, a playback location when a user interrupts playback of Real PlayList or Virtual PlayList is stored in resume-mark defined in PlayListMark() ( <a href="mailto:drawing 42">drawing 42</a>, <a href="mailto:drawing 43">drawing 43</a>). [0125] <a href="mailto:Drawing 17">Drawing 17</a> is drawing showing the syntax of ResumeVolume(). For explaining the syntax of ResumeVolume() shown in <a href="mailto:drawing 17">drawing 17</a>, valid\_flag shows that the resume\_PlayList\_name field is invalid, when it is shown that the resume\_PlayList\_name field is effective when this 1-bit flag is set to 1 and this flag is set to 0.

[0126] 10 bytes of field of resume\_PlayList\_name shows the file name of Real PlayList by which resume should be carried out, or Virtual PlayList.
[0127] UIAppInfoVolume in the syntax of DVRVolume() shown in <u>drawing 16</u>
The parameter of the user interface application about volume is stored. The 8-bit field of character\_set shows the coding approach of the character alphabetic character encoded in the Volume\_name field for <u>drawing 18</u> to be drawing showing the syntax of UIAppInfoVolume, and explain the semantics. The coding approach corresponds to the value shown in <u>drawing 19</u>.
[0128] Eight bit fields of name\_length show the cutting tool length of a volume name shown in the Volume\_name field. The field of Volume\_name shows the name of volume. The byte count of the left in this field to a name\_length number is an effective character alphabetic character, and it shows the name

of volume. In the Volume\_name field, as for the value after these effective

characters alphabetic character, what kind of value may be in close.

[0129] Volume\_protect\_flag is a flag which shows whether the contents in volume may be shown without restricting to a user. Only when this flag is set to 1 and a user is able to input an PIN number (password) correctly, showing a user the contents of that volume (reproduced) is permitted. When this flag is set to 0, even if a user does not input an PIN number, showing a user the contents of that volume is permitted.

[0130] If a user is able to input an PIN number correctly even if first this flag is set to 0 or this flag is set to 1, when a user inserts a disk in a player, as for the record regenerative apparatus 1, the list of PlayList in that disk will be displayed. The playback limit of each PlayList is unrelated to volume\_protect\_flag, and it is shown by playback\_control\_flag defined in UIAppInfoPlayList().

[0131] PIN consists of figures to four 0 thru/or 9, and each figure is encoded according to ISO/IEC 646. The field of ref\_thumbnail\_index shows the information on the thumbnail image added to volume. In the case of the value whose ref\_thumbnail\_index field is not 0xFFFF, the thumbnail image is added to the volume and the thumbnail image is stored in the menu.thum file. The image is referred to using the value of ref\_thumbnail\_index in a menu.thum file. the ref\_thumbnail\_index field -- 0xFFFF it is -- a case -- the volume -- a thumbnail image -- adding -- having -- \*\*\*\* -- things -- being shown .

[0132] Next, TableOfPlayLists() in the syntax of info.dvr shown in drawing 15 is explained. TableOfPlayLists() stores the file name of PlayList (Real PlayList and Virtual PlayList). All the PlayList files currently recorded on volume are

[0133] version\_number of TableOfPlayLists shows four character alphabetic characters which show the version number of this TableOfPlayLists for drawing 20 to be drawing showing the syntax of TableOfPlayLists(), and explain that syntax. version\_number must be encoded with "0045" according to ISO 646.

included in TableOfPlayList(). TableOfPlayLists() shows the default playback

sequence of PlayList in volume.

[0134] length is an integer without a 32-bit sign which shows the byte count of TableOfPlayLists() from immediately after this length field to the last of

TableOfPlayLists(). The 16-bit field of number\_of\_PlayLists shows the loop count of for-loop containing PlayList\_file\_name. This figure must be equal to the number of PlayList(s) currently recorded on volume. 10 bytes of figure of PlayList\_file\_name shows the file name of PlayList.

[0135] <u>Drawing 21</u> is drawing showing another configuration of the syntax of TableOfPlayLists(). The syntax shown in <u>drawing 21</u> is considered as the configuration in which UIAppinfoPlayList (after-mentioned) was included in the syntax shown in <u>drawing 20</u>. Thus, it becomes possible only by reading TableOfPlayLists to create a menu screen by considering as the configuration in which UIAppinfoPlayList was included. Here, the following explanation is given noting that the syntax shown in <u>drawing 20</u> is used.

[0136] MakersPrivateData in the syntax of info.dvr shown in drawing 15 is explained. MakersPrivateData is prepared so that the manufacturer of the record regenerative apparatus 1 can insert a manufacturer's private data into MakersPrivateData() for the special application of each company. Each manufacturer's private data has maker\_ID standardized in order to identify the manufacturer who defined it. MakersPrivateData() may also contain one or more maker\_ID.

[0137] When a predetermined manufacturer wants to insert private data and other manufacturers' private data is already contained in MakersPrivateData(), other manufacturers add new private data into MakersPrivateData() rather than eliminate the old private data which already exists. Thus, in the gestalt of this operation, two or more manufacturers' private data carries out as [ be / being contained in one MakersPrivateData() / possible ].

[0138] <u>Drawing 22</u> is drawing showing the syntax of MakersPrivateData. version\_number shows four character alphabetic characters which show the version number of this MakersPrivateData() for explaining the syntax of MakersPrivateData shown in <u>drawing 22</u>. version\_number must be encoded with "0045" according to ISO 646. length shows the 32-bit unsigned integer which shows the byte count of MakersPrivateData() from immediately after this length field to the last of MakersPrivateData().

[0139] mpd\_blocks\_start\_address shows the head byte address of the first mpd\_block() by making the relative byte count from the cutting tool of the

head of MakersPrivateData() into a unit. A relative byte count is counted from zero. number of maker\_entries is a 16-bit unsigned integer which gives the number of entries of the manufacturer private data contained in MakersPrivateData(). Two or more manufacturer private data which have the value of the same maker\_ID in MakersPrivateData() must not exist. [0140] mpd\_block\_size is a 16-bit unsigned integer which gives the magnitude of one mpd\_block by making 1024 bytes into a unit. For example, if it becomes mpd\_block\_size=1, it shows that the magnitude of one mpd\_block is 1024 bytes. number\_of\_mpd\_blocks is a 16-bit unsigned integer which gives the number of mpd block contained in MakersPrivateData(). maker\_ID is a 16-bit unsigned integer which shows the manufacture manufacturer of the DVR system which created the manufacturer private data. The value encoded by maker\_ID is specified by the licenser of this DVR format. [0141] maker\_model\_code is a 16-bit unsigned integer which shows the model number code of the DVR system which created the manufacturer private data. The value encoded by maker\_model\_code is set up by the carrier beam manufacture manufacturer in the license of this format.

model number code of the DVR system which created the manufacturer private data. The value encoded by maker\_model\_code is set up by the carrier beam manufacture manufacturer in the license of this format. start\_mpd\_block\_number is a 16-bit unsigned integer which shows the number of mpd\_block by which the manufacturer private data is started. The aryne of the initial data of manufacturer private data must be carried out to the head of mpd\_block. start\_mpd\_block\_number corresponds to the variable j in for-loop of mpd\_block.

[0142] mpd\_length is a 32-bit unsigned integer which shows the magnitude of manufacturer private data per cutting tool. mpd\_block is a field in which manufacturer private data is stored. All mpd\_block in MakersPrivateData() must be the same sizes.

[0143] Next, xxxxx.rpls and yyyyy.vpls will be explained if it puts in another way about Real PlayList file and Virtual PlayList file. <u>Drawing 23</u> is drawing showing the syntax of xxxxx.rpls (Real PlayList) or yyyyy.vpls (Virtual PlayList). xxxxx.rpls and yyyyy.vpls have the same syntax configuration. xxxxx.rpls and yyyyy.vpls consist of three objects, respectively, and they are PlayList(), PlayListMark(), and MakersPrivateData().

[0144] PlayListMark\_Start\_address shows the start address of PlayListMark()

by making the relative byte count from the cutting tool of the head of a PlayList file into a unit. A relative byte count is counted from zero. [0145] MakersPrivateData\_Start\_address shows the start address of MakersPrivateData() by making the relative byte count from the cutting tool of the head of a PlayList file into a unit. A relative byte count is counted from zero.

[0146] padding\_word (padding WORD) is inserted according to the syntax of a PlayList file, and N1 and N2 are the positive integers of zero or arbitration. You may make it each padding WORD take any value.

[0147] Here, although already explained simple, PlayList is explained further. Refer to the playback section in all Clip(s) except Bridge-Clip (aftermentioned) for all Real PlayList in a disk. And two or more RealPlayList(s) must not make the playback section shown by those PlayItem(s) overlap in the same Clip.

[0148] As shown, Real PlayList to which all Clip(s) correspond exists in explaining further with reference to <u>drawing 24</u> at <u>drawing 24</u> (A). This regulation is followed after an editing task is performed, as shown in <u>drawing 24</u> (B). therefore, all Clip(s) -- which -- it is -- surely viewing and listening is possible by referring to Real PlayList.

[0149] As shown in <u>drawing 24</u> (C), the playback section of Virtual PlayList must be included in the playback section of Real PlayList, or the playback section of Bridge-Clip. Bridge-Clip referred to at no Virtual PlayList must not exist in a disk.

[0150] Although Real PlayList includes the list of PlayItem, it must not contain SubPlayItem. When CPI\_type Virtual PlayList is indicated to be in PlayList() including the list of PlayItem is EP\_map type and PlayList\_type is 0 (PlayList containing video and an audio), Virtual PlayList can contain one SubPlayItem. In PlayList() in the gestalt of this operation, SubPlayIte must be used only for the object of postrecording of an audio and the number of SubPlayItem(s) which one Virtual PlayList has must be 0 or 1.

[0151] Next, PlayList is explained. <u>Drawing 25</u> is drawing showing the syntax of PlayList. They are four character alphabetic characters in which version\_number shows the version number of this PlayList() for explaining the

syntax of PlayList shown in <u>drawing 25</u> . version\_number must be encoded with "0045" according to ISO 646. length is a 32-bit unsigned integer which shows the byte count of PlayList() from immediately after this length field to the last of PlayList(). PlayList\_type is the 8-bit field which shows the type of this PlayList, and shows that example to <u>drawing 26</u> . [0152] CPI\_type is a 1-bit flag and shows the value of CPI\_type of Clip referred to by PlayItem() and SubPlayItem(). All Clip(s) referred to by one PlayList must have the the same value of CPI\_type defined in those CPI(). number\_of\_PlayItems is the 16-bit field which shows the number of PlayItem(s) in PlayList.

[0153] PlayItem\_id corresponding to predetermined PlayItem() is defined in for-loop containing PlayItem() by the sequence that the PlayItem() appears. PlayItem\_id is started from 0. number\_of\_SubPlayItems is the 16-bit field which shows the number of SubPlayItem(s) in PlayList. This value is 0 or 1. The pass (audio stream pass) of an additional audio stream is a kind of subpass.

[0154] Next, UIAppInfoPlayList of the syntax of PlayList shown in drawing 25 is explained. UIAppInfoPlayList stores the parameter of the user interface application about PlayList. Drawing 27 is drawing showing the syntax of UIAppInfoPlayList. For explaining the syntax of UIAppInfoPlayList shown in drawing 27, character\_set is the 8-bit field and shows the coding approach of the character alphabetic character encoded in the PlayList\_name field. The coding approach corresponds to the value based on the table shown in drawing 19.

[0155] name\_length is eight bit fields and shows the cutting tool length of the PlayList name shown in the PlayList\_name field. The field of PlayList\_name shows the name of PlayList. The byte count of the left in this field to a name\_length number is an effective character alphabetic character, and it shows the name of PlayList. In the PlayList\_name field, as for the value after these effective characters alphabetic character, what kind of value may be in close.

[0156] record\_time\_and\_date is the 56-bit field in which time when PlayList is recorded is stored. This field encodes 14 figures by 4-bit Binary Coded Decimal (BCD) about a /part / second at the time of year / moon / day/. For

example, 2001/12/23:01:02:03 It encodes with "0x20011223010203." [0157] duration is the 24-bit field which showed the total playback time amount of PlayList in the unit of time amount / part / second. This field encodes six figures by 4-bit Binary CodedDecimal (BCD). For example, 01:45:30 is encoded with "0x014530."

[0158] valid\_period is the 32-bit field which shows the period when PlayList is effective. This field encodes eight figures by 4-bit Binary Coded Decimal (BCD). For example, the record regenerative apparatus 1 is used as it said that automatic elimination of the PlayList over which this shelf-life passed was carried out. For example, 2001/05/07 It encodes with "0x20010507."

[0159] maker\_id is a 16-bit unsigned integer which shows the manufacturer of the DVR player (record regenerative apparatus 1) which updated the PlayList at the end. The value encoded by maker\_id is assigned by the licenser of a DVR format. maker\_code is a 16-bit unsigned integer which shows the model number of the DVR player which updated the PlayList at the end. The value encoded by maker\_code is decided by the carrier beam manufacturer in the license of a DVR format.

[0160] The PlayList is reproduced, only when the flag of playback\_control\_flag is set to 1 and a user is able to input an PIN number correctly. When this flag is set to 0, even if a user does not input an PIN number, a user can view and listen to that PlayList.

[0161] As a table is shown in <u>drawing 28</u> (A), when write\_protect\_flag is set to 1, write\_protect\_flag is removed, and the content of the PlayList is not eliminated and changed. When this flag is set to 0, a user can eliminate and change that PlayList freely. When this flag is set to 1, before a user eliminates, edits or overwrites that PlayList, the record regenerative apparatus 1 displays a message which is reconfirmed to a user.

[0162] Virtual PlayList which Real PlayList by which write\_protect\_flag is set to 0 exists, and refers to Clip of the Real PlayList exists, and write\_protect\_flag of the Virtual PlayList may be set to 1. "Minimize" [ regenerative apparatus / it warns a user of existence of Above Virtual PlayList, or / the Real PlayList ] before the record regenerative apparatus 1 eliminates the Real PlayList when a user is going to eliminate RealPlayList.

[0163] As is\_played\_flag is shown in <u>drawing 28</u> (B), when it is shown that it was reproduced at once after the PlayList was recorded when the flag was set to 1 and it is set to 0, the PlayList shows not being reproduced once, after being recorded.

[0164] archive is the 2-bit field which shows whether the PlayList is original or it is copied, as shown in drawing 28 (C). ref\_thumbnail\_index The field shows the information on a thumbnail image that PlayList is represented. In the case of the value whose ref\_thumbnail\_index field is not 0xFFFF, the thumbnail image representing PlayList is added to the PlayList, and the thumbnail image is menu.thum. It is stored in the file. The image is referred to using the value of ref\_thumbnail\_index in a menu.thum file. the ref\_thumbnail\_index field -- 0xFFFF it is -- a case -- the PlayList -- PlayList -- representing -- a thumbnail - an image -- adding -- having -- \*\*\*\*\*

[0165] Next, PlayItem is explained. One PlayItem() contains the following data fundamentally. When CPI\_type defined in the pair of IN\_time for specifying Clip\_information\_file\_name for specifying the file name of Clip and the playback section of Clip and OUT\_time and PlayList() is EP\_map type, they are STC\_sequence\_id which IN\_time and OUT\_time refer to, and connection\_condition which shows the condition of connection between PlayItem to precede and current PlayItem.

[0166] Those PlayItem(s) are arranged in on the global time-axis of PlayList without the gap of time amount, or overlap by the single tier when PlayList consists of two or more PlayItem(s). CPI\_type defined in PlayList() is EP\_map type, and the pair of IN\_time defined in the PlayItem when the present PlayItem does not have BridgeSequence(), and OUT\_time must point out the time amount on the same STC continuation section specified by STC\_sequence\_id. Such an example is shown in drawing 29. [0167] CPI\_type defined in PlayList() is EP\_map type, and drawing 30 shows the case where the regulation explained below is applied, when the present PlayItem has BridgeSequence(). IN\_time (what is indicated to be IN\_time1 in

drawing) of PlayItem preceded with current PlayItem has pointed out the time

amount on the STC continuation section specified by STC\_sequence\_id of

PlayItem to precede. OUT\_time (what is indicated to be OUT\_time1 in

drawing) of PlayItem to precede has pointed out the time amount in Bridge-Clip specified in BridgeSequenceInfo() of current PlayItem. This OUT\_time must follow the coding limit mentioned later.

[0168] IN\_time (what is indicated to be IN\_time2 in drawing) of current PlayItem has pointed out the time amount in Bridge-Clip specified in BridgeSequenceInfo() of current PlayItem. This IN\_time must also follow the coding limit mentioned later. OUT\_time (what is indicated to be OUT\_time2 in drawing) of PlayItem of current PlayItem has pointed out the time amount on the STC continuation section specified by STC\_sequence\_id of current PlayItem.

[0169] As shown in <u>drawing 31</u>, when CPI\_type of PlayList() is TU\_map type, the pair of IN\_time of PlayItem and OUT\_time has pointed out the time amount on the same Clip AV stream.

[0170] The syntax of PlayItem comes to be shown in <u>drawing 32</u>. The field of Clip\_Information\_file\_name shows the file name of ClipInformation file for explaining the syntax of PlayItem shown in <u>drawing 32</u>. Clip\_stream\_type defined in ClipInfo() of this Clip Information file must show Clip AV stream. [0171] STC\_sequence\_id is the 8-bit field and shows STC\_sequence\_id of the STC continuation section which PlayItem refers to. When CPI\_type specified in PlayList() is TU\_map type, these eight bit fields have no semantics, but are set to 0. IN\_time is 32 bit fields and stores the playback start time of PlayItem. The semantics of IN\_time changes with CPI\_type defined in PlayList(), as shown in drawing 33.

[0172] OUT\_time is 32 bit fields and stores the playback end time of PlayItem. The semantics of OUT\_time changes with CPI\_type defined in PlayList(), as shown in drawing 34.

[0173] Connection\_Condition is the 2-bit field which shows the connection condition between PlayItem to precede as shown in <u>drawing 35</u>, and the present PlayItem. <u>Drawing 36</u> is drawing explaining each condition of Connection\_Condition shown in drawing 35.

[0174] Next, BridgeSequenceInfo is explained with reference to <u>drawing 37</u>. BridgeSequenceInfo() is the attached information on current PlayItem, and has the information shown below. Bridge\_Clip\_Information\_file\_name which

specifies Clip Information file ( <u>drawing 45</u> ) corresponding to a Bridge-Clip AV stream file and it is included.

[0175] Moreover, it is the address of the source packet on Clip AV stream which PlayItem to precede refers to, and the source packet of the beginning of a Bridge-Clip AV stream file is connected following this source packet. This address is called RSPN\_exit\_from\_previous\_Clip. It is the address of the source packet on Clip AV stream which further current PlayItem refers to, and the source packet of the last of a Bridge-Clip AV stream file is connected before this source packet. This address is called RSPN\_enter\_to\_current\_Clip. [0176] In drawing 37, RSPN\_arrival\_time\_discontinuity shows the address of the source packet which has the break point of arrival time base in a the Bridge-Clip AVstream file. This address is defined in ClipInfo() ( drawing 46 ). [0177] Drawing 38 is drawing showing the syntax of BridgeSequenceinfo. The field of Bridge\_Clip\_Information\_file\_name shows the file name of Clip Information file corresponding to a Bridge-Clip AV stream file for explaining the syntax of BridgeSequenceinfo shown in drawing 38. Clip\_stream\_type defined in ClipInfo() of this Clip Information file must show 'Bridge-Clip AV stream'.

[0178] 32 bit fields of RSPN\_exit\_from\_previous\_Clip are the relative addresses of the source packet on Clip AV stream which PlayItem to precede refers to, and the source packet of the beginning of a Bridge-Clip AV stream file is connected following this source packet. RSPN\_exit\_from\_previous\_Clip is magnitude which makes a source packet number a unit, and counts the value of offset\_SPN defined in ClipInfo() from the source packet of the beginning of the Clip AV stream file which PlayItem to precede refers to as initial value.

[0179] 32 bit fields of RSPN\_enter\_to\_current\_Clip are the relative addresses of the source packet on Clip AV stream which current PlayItem refers to, and the source packet of the last of a Bridge-Clip AV stream file is connected before this source packet. RSPN\_exit\_from\_previous\_Clip is magnitude which makes a source packet number a unit, and counts the value of offset\_SPN defined in ClipInfo() from the source packet of the beginning of the Clip AV stream file which current PlayItem refers to as initial value.

[0180] Next, SubPlayItem is explained with reference to drawing 39. The activity of SubPlayItem() is allowed only when CPI\_type of PlayList() is EP map type. In the gestalt of this operation, SubPlayItem presupposes that it is used only for the object of postrecording of an audio. SubPlayItem() contains the data shown below. First, Clip\_information\_file\_name for specifying Clip which sub path in PlayList refers to is included. [0181] Moreover, SubPath\_IN\_time for specifying the playback section of sub path in Clip SubPath OUT time is included. Furthermore, sync\_PlayItem\_id for specifying the time of day in which sub path carries out playback initiation on the time-axis of main path sync\_start\_PTS\_of\_PlayItem is included. Clip AV stream of the audio referred to at sub path must not contain an STC break point (break point of system time base). The clock of the audio sample of Clip used for sub path is locked by the clock of the audio sample of main path. [0182] Drawing 40 is drawing showing the syntax of SubPlayItem. The field of Clip Information\_file\_name shows the file name of Clip Information file for explaining the syntax of SubPlayItem shown in drawing 40, and it is used by sub path in PlayList. Clip\_stream\_type defined in ClipInfo() of this Clip Information file must show Clip AV stream.

[0183] The 8-bit field of SubPath\_type shows the type of sub path. Here, as shown in <u>drawing 41</u>, only '0x00' is set up but other values are secured for the future.

[0184] The 8-bit field of sync\_PlayItem\_id shows PlayItem\_id of PlayItem in which the time of day sub path carries out [ time of day ] playback initiation on the time-axis of main path is contained. The value of PlayItem\_id corresponding to predetermined PlayItem is defined in PlayList() (refer to drawing 25).

[0185] The 32-bit field of sync\_start\_PTS\_of\_PlayItem shows the time of day in which sub path carries out playback initiation on the time-axis of main path, and shows 32 bits of high orders of PTS on PlayItem referred to by sync\_PlayItem\_id (Presentaiotn Time Stamp). 32 bit fields of SubPath\_IN\_time store the playback start time of Sub path. SubPath\_IN\_time shows 32 bits of high orders of PTS of 33 bit length corresponding to the first presentation unit in Sub Path.

[0186] 32 bit fields of SubPath\_OUT\_time store the playback end time of Sub path. SubPath\_OUT\_time shows 32 bits of high orders of the value of Presenation\_end\_TS computed by the degree type. Presentation\_end\_TS = PTS\_out+AU\_duration -- here, PTS\_out is PTS of 33 bit length corresponding to the presentation unit of the last of SubPath. AU\_duration is the display period of the 90kHz unit of the presentation unit of the last of SubPath. [0187] Next, PlayListMark() in the syntax of xxxxx.rpls shown in drawing 23 and yyyyy.vpls is explained. The mark information about PlayList is stored in this PlayListMark. Drawing 42 is drawing showing the syntax of PlayListMark. They are four character alphabetic characters in which version\_number shows the version number of this PlayListMark() for explaining the syntax of PlayListMark shown in drawing 42 . version\_number must be encoded with "0045" according to ISO 646.

[0188] length is a 32-bit unsigned integer which shows the byte count of PlayListMark() from immediately after this length field to the last of PlayListMark(). number\_of\_PlayList\_marks is a 16-bit unsigned integer which shows the number of the mark currently stored in PlayListMark. number\_of\_PlayList\_marks You may be 0. mark\_type is the 8-bit field which shows the type of a mark, and is encoded according to the table shown in drawing 43.

[0189] 32 bit fields of mark\_time\_stamp store the time stump in which the point with which the mark was specified is shown. The semantics of mark\_time\_stamp changes with CPI\_type defined in PlayList(), as shown in drawing 44. PlayItem\_id is the 8-bit field which specifies PlayItem on which the mark is put. The value of PlayItem\_id corresponding to predetermined PlayItem is defined in PlayList() (refer to drawing 25).

[0190] The 8-bit field of character\_set shows the coding approach of the character alphabetic character encoded by the mark\_name field. The coding approach corresponds to the value shown in <u>drawing 19</u>. Eight bit fields of name\_length show the cutting tool length of the mark name shown in the Mark\_name field. The field of mark\_name shows the name of a mark. The byte count of the left in this field to a name\_length number is an effective character alphabetic character, and it shows the name of a mark. As for the

value after these effective characters alphabetic character, what kind of value may be set up in the Mark\_name field.

[0191] The field of ref\_thumbnail\_index shows the information on the thumbnail image added to a mark. In the case of the value whose ref thumbnail\_index field is not 0xFFFF, the thumbnail image is added to the mark and the thumbnail image is stored in the mark.thmb file. The image is referred to using the value of ref\_thumbnail\_index in a mark.thmb file (aftermentioned), the ref thumbnail index field -- 0xFFFF it is -- a case -- the mark -- a thumbnail image -- adding -- having -- \*\*\*\* -- things -- being shown . [0192] Next, Clip information file is explained. zzzzz.clpi (Clip information file file) consists of six objects, as shown in drawing 45. They are ClipInfo(), STC\_Info(), ProgramInfo(), CPI(), ClipMark(), and MakersPrivateData(). "zzzzz" of the digit string with the same Clip Information file corresponding to AV stream (a Clip AV stream or Bridge-Clip AV stream) and it is used. [0193] ClipInfo\_Start\_address shows the start address of ClipInfo() for explaining the syntax of zzzzz.clpi (Clip information file file) shown in drawing 45 by making the relative byte count from the cutting tool of the head of a zzzzz.clpi file into a unit. A relative byte count is counted from zero. [0194] STC\_Info\_Start\_address shows the start address of STC\_Info() by making the relative byte count from the cutting tool of the head of a zzzzz.clpi file into a unit. A relative byte count is counted from zero.

ProgramInfo\_Start\_address shows the start address of ProgramInfo() by making the relative byte count from the cutting tool of the head of a zzzzz.clpi file into a unit. A relative byte count is counted from zero. CPI\_Start\_address shows the start address of CPI() by making the relative byte count from the cutting tool of the head of a zzzzz.clpi file into a unit. A relative byte count is counted from zero.

[0195] ClipMark\_Start\_address shows the start address of ClipMark() by making the relative byte count from the cutting tool of the head of a zzzzz.clpi file into a unit. A relative byte count is counted from zero.

MakersPrivateData\_Start\_address shows the start address of MakersPrivateData () by making the relative byte count from the cutting tool of the head of a zzzzz.clpi file into a unit. A relative byte count is counted from

zero. padding\_word (padding WORD) is inserted according to the syntax of a zzzzz.clpi file. N1, N2, N3, N4, and N5 must be the positive integers of zero or arbitration. As for each padding WORD, any value may be made to be taken. [0196] Next, ClipInfo is explained. <u>Drawing 46</u> is drawing showing the syntax of ClipInfo. ClipInfo() stores the attribute information on AV stream file (a Clip AV stream or Bridge-Clip AV stream file) corresponding to it.

[0197] They are four character alphabetic characters in which version\_number shows the version number of this ClipInfo() for explaining the syntax of ClipInfo shown in drawing 46. version\_number must be encoded with "0045" according to ISO 646. length is a 32-bit unsigned integer which shows the byte count of ClipInfo() from immediately after this length field to the last of ClipInfo(). The 8-bit field of Clip\_stream\_type shows the type of AV stream corresponding to a Clip Information file, as shown in drawing 47. About the stream type of each type of AV stream, it mentions later.

[0198] The 32-bit field of offset\_SPN gives the offset value of the source packet number about the source packet of the beginning of AV stream (Clip AV stream or Bridge-Clip AV stream) file. This offset\_SPN must be 0 when AV stream file is first recorded on a disk.

[0199] As shown in <u>drawing 48</u>, when the first part of AV stream file is eliminated by edit, offset\_SPN is very good in values other than zero. The relative source packet number (relative address) which refers to offset\_SPN with the gestalt of this operation is often RSPN\_xxx (xxx deforms.). It is described by in the form of example .RSPN\_EP\_start in syntax. A relative source packet number is magnitude which makes a source packet number a unit, and counts the value of offset\_SPN as initial value from the source packet of the beginning of AV stream file.

[0200] The number (SPN\_xxx) of the source packets to the source packet referred to by the relative source packet number from the source packet of the beginning of AV stream file is computed by the degree type.

An example in case offset\_SPN is 4 is shown in SPN\_xxx = RSPN\_xxx-offset\_SPN drawing 48.

[0201] TS\_recording\_rate -- a 24-bit unsigned integer -- it is -- this value -- a DVR drive (write-in section 22) -- or the bit rate of required I/O of AV stream

from a DVR drive (read-out section 28) is given. record\_time\_and\_date is the 56-bit field in which time when AV stream corresponding to Clip is recorded is stored, and encodes 14 figures by 4-bit Binary Coded Decimal (BCD) about a /part / second at the time of year / moon / day/. For example, 2001/12/23:01:02:03 are encoded with "0x20011223010203."

[0202] duration is the 24-bit field which showed the total playback time amount of Clip in the unit of time amount / part / second based on an arrival timer clock. This field encodes six figures by 4-bit Binary Coded Decimal (BCD). For example, 01:45:30 is encoded with "0x014530."

[0203] The flag of time\_controlled\_flag shows the recording mode of AV stream file. When this time\_controlled\_flag is 1, a recording mode must fulfill the conditions which show that it is the mode in which it is recorded to the

TS\_average\_rate\*192/188\*(t-start\_time)-alpha <= size\_clip (t) -<=TS\_average\_rate\*192/188\*(t-start\_time) +alpha -- here -- TS\_average\_rate
-- the average bit rate of the transport stream of AV stream file -bytes/second a unit -- a table -- it is a thing the bottom.

time amount progress after recording as a file size is proportional, and are

shown in a degree type.

[0204] Moreover, in a top type, t shows the time amount expressed per second, and start\_time is time of day when the source packet of the beginning of AV stream file is recorded, and is expressed per second. size\_clip (t), When the size of AV stream file in time of day t is expressed per cutting tool, for example, ten source packets are recorded by time of day t from start\_time, size\_clip (t) is 10\*192 bytes. alpha is a constant depending on TS\_average\_rate.

[0205] When time\_controlled\_flag is set to 0, not controlling the recording mode so that the file size of AV stream is proportional to time amount progress of record is shown. For example, this is the case where transparent record of the input transport stream is carried out.

[0206] When, as for TS\_average\_rate, time\_controlled\_flag is set to 1, this 24-bit field shows the value of TS\_average\_rate used by the top formula. When time\_controlled\_flag is set to 0, this field has no semantics but must be set to 0. For example, the transport stream of a Variable Bit Rate is encoded by the

procedure shown below. A transformer portrait is first set to the value of TS\_recording\_rate. Next, a video stream is encoded with a Variable Bit Rate. And a transport packet is intermittently encoded by not using Nur Paquette. [0207] 32 bit fields of RSPN\_arrival\_time\_discontinuity are the relative addresses of the location which the discontinuity of arrival time base generates on a Bridge-Clip AV stream file. RSPN\_arrival\_time\_discontinuity is magnitude which makes a source packet number a unit, and is ClipInfo() from the source packet of the beginning of a Bridge-Clip AV stream file. The value of offset\_SPN set and defined is counted as initial value. The absolute address in the inside of the Bridge-Clip AV stream file is computed based on SPN\_xxx = RSPN\_xxx-offset\_SPN mentioned above.

[0208] The 144-bit field of reserved\_for\_system\_use is reserved for systems. When the flag of is\_format\_identifier\_valid is 1, it is shown that the field of format\_identifier is effective. When the flag of is\_original\_network\_ID\_valid is 1, it is shown that the field of original\_network\_ID is effective. When the flag of is\_transport\_stream\_ID\_valid is 1, it is shown that the field of transport\_stream\_ID is effective. When the flag of is\_servece\_ID\_valid is 1, it is shown that the field of servece\_ID is effective.

[0209] When the flag of is\_country\_code\_valid is 1, it is shown that the field of country\_code is effective. 32 bit fields of format\_identifier show the value of format\_identifier which registration deascriotor (it defines as ISO/IEC 13818-1) has in a transport stream. 16 bit fields of original\_network\_ID show the value of original\_network\_ID defined in the transport stream. 16 bit fields of transport\_stream\_ID show the value of transport\_stream\_ID defined in the transport stream.

[0210] 16 bit fields of servece\_ID show the value of servece\_ID defined in the transport stream. The 24-bit field of country\_code shows the country code defined by ISO3166. Each character alphabetic character is encoded by ISO 8859-1. For example, Japan is expressed as "JPN" and encoded with "0x4A 0x500x4E." stream\_format\_name is 16 character codes of ISO-646 which show the name of the format engine which is doing the stream definition of a transport stream. As for the invalid cutting tool in this field, value'0xFF' is set. [0211] format\_identifier, original\_network\_ID, transport\_stream\_ID, servece\_ID,

country\_code, and stream\_format\_name can show the service provider of a transport stream, and, thereby, can recognize a coding limit of an audio or a video stream, and the stream definition of the specification of SI (service information), or private data streams other than an audio video stream. Such information can be used, in order that a decoder may perform initial setting of a decoder system before decoding initiation whether the stream can be decoded and when it can decode and.

[0212] Next, STC\_Info is explained. Here, the time amount section which does not contain the break point (break point of system time base) of STC in an MPEG-2 transport stream is called STC\_sequence, and STC\_sequence is specified with the value of STC\_sequence\_id in Clip. Drawing 50 is drawing explaining the STC section [ \*\*\*\* ]. The value of the STC same in the same STC\_sequence never appears (however, the maximum time amount length of Clip is restricted so that it may mention later). Therefore, the same value of PTS also never appears in the same STC\_sequence. When AV stream contains the STC break point of N (N> 0) individual, the system time base of Clip is divided into STC\_sequence of an individual (N+1).

[0213] STC\_Info stores the address of the location which the discontinuity (discontinuity of system time base) of STC generates. RSPN\_STC\_start shows the address, and k-th STC\_sequence (k>=0) except the last STC\_sequence begins from the time of day when the source packet referred to by k-th RSPN\_STC\_start arrived, and finishes with the time of day when the source packet referred to by RSPN\_STC\_start of eye watch (k+1) arrived so that it may explain with reference to <u>drawing 51</u>. The last STC\_sequence begins from the time of day when the source packet referred to by the last RSPN\_STC\_start arrived, and is ended at the time of day when the last source packet arrived.

[0214] <u>Drawing 52</u> is drawing showing the syntax of STC\_Info. They are four character alphabetic characters in which version\_number shows the version number of this STC\_Info() for explaining the syntax of STC\_Info shown in <u>drawing 52</u> . version\_number must be encoded with "0045" according to ISO 646.

[0215] length is a 32-bit unsigned integer which shows the byte count of

STC\_Info() from immediately after this length field to the last of STC\_Info(). When CPI\_type of CPI() shows TU\_map type, this length field may set zero. When CPI\_type of CPI() shows EP\_map type, num\_of\_STC\_sequences must be one or more values.

[0216] The 8-bit unsigned integer of num\_of\_STC\_sequences shows the number of STC\_sequence(s) in the inside of Clip. This value shows the loop count of for-loop following this field. STC\_sequence\_id corresponding to predetermined STC\_sequence is defined in for-loop containing RSPN STC start by the sequence that RSPN\_STC\_start corresponding to the STC sequence appears. STC\_sequence\_id is started from 0. [0217] 32 bit fields of RSPN\_STC\_start show the address which STC sequence starts on AV stream file. RSPN\_STC\_start shows the address which the break point of system time base generates in AV stream file. RSPN\_STC\_start is good also as a relative address of a source packet which has PCR of the beginning of new system time base in AV stream. RSPN\_STC\_start is magnitude which makes a source packet number a unit, and counts the value of offset\_SPN defined in ClipInfo() from the source packet of the beginning of AV stream file as initial value. The absolute address in the inside of the AV stream file is computed by SPN\_xxx = RSPN\_xxx-offset\_SPN already mentioned above.

[0218] Next, ProgramInfo in the syntax of zzzzz.clip shown in drawing 45 is explained. The time amount section which has the following description in Clip is called program\_sequence for explaining here, referring to drawing 53. First, the value of PCR\_PID does not change. Next, the number of video elementary streams does not change. Moreover, the encoded information defined by the value and VideoCodingInfo of PID about each video stream does not change. Furthermore, the number of audio elementary streams does not change. Moreover, the encoded information defined by the value and AudioCodingInfo of PID about each audio stream does not change.

[0219] program\_sequence has only one system time base in the same time of day. program\_sequence has only one PMT in the same time of day. ProgramInfo() stores the address of the location which program\_sequence starts. RSPN\_program\_sequence\_start shows the address.

[0220] <u>Drawing 54</u> is drawing showing the syntax of ProgramInfo. They are four character alphabetic characters in which version\_number shows the version number of this ProgramInfo() for explaining SHINTAKU of ProgramInfo shown in <u>drawing 54</u> . version\_number must be encoded with "0045" according to ISO 646.

[0221] length is a 32-bit unsigned integer which shows the byte count of ProgramInfo() from immediately after this length field to the last of ProgramInfo(). When CPI\_type of CPI() shows TU\_map type, this length field may be set to zero. When CPI\_type of CPI() shows EP\_map type, number of programs must be one or more values.

[0222] The 8-bit unsigned integer of number\_of\_program\_sequences shows the number of program\_sequence in the inside of Clip. This value shows the loop count of for-loop following this field. When program\_sequence does not change in Clip, number\_of\_program\_sequences must have 1 set. 32 bit fields of RSPN\_program\_sequence\_start are the relative addresses of the location which a program sequence starts on AV stream file.

[0223] RSPN\_program\_sequence\_start is magnitude which makes a source packet number a unit, and counts the value of offset\_SPN defined in ClipInfo() from the source packet of the beginning of AV stream file as initial value. The absolute address in the inside of the AV stream file is computed by SPN\_xxx = RSPN\_xxx-offset\_SPN. A RSPN\_program\_sequence\_start value must appear in ascending order in for-loop of syntax.

[0224] 16 bit fields of PCR\_PID show PID of transport Paquette including the PCR field effective in the program\_sequence. Eight bit fields of number\_of\_videos show the loop count of video\_stream\_PID and for-loop containing VideoCodingInfo(). Eight bit fields of number\_of\_audios show the loop count of audio\_stream\_PID and for-loop containing AudioCodingInfo(). 16 bit fields of video\_stream\_PID show PID of transport Paquette containing a video stream effective in the program\_sequence. VideoCodingInfo() following this field must explain the content of the video stream referred to by that video\_stream\_PID.

[0225] 16 bit fields of audio\_stream\_PID show PID of transport Paquette containing an audio stream effective in the program\_sequence.

AudioCodingInfo() following this field must explain the content of the video stream referred to by that audio\_stream\_PID.

[0226] In addition, the sequence that the value of video\_stream\_PID appears in for-loop of syntax must be equal to the sequence that PID of a video stream is encoded in PMT effective in the program\_sequence. Moreover, the sequence that the value of audio\_stream\_PID appears in for-loop of syntax must be equal to the sequence that PID of an audio stream is encoded in PMT effective in the program\_sequence.

[0227] <u>Drawing 55</u> is drawing showing the syntax of VideoCodingInfo in the syntax of Programinfo shown in <u>drawing 54</u>. For explaining the syntax of VideoCodingInfo shown in <u>drawing 55</u>, eight bit fields of video\_format show the video format corresponding to video\_stream\_PID in ProgramInfo(), as shown at drawing 56.

[0228] Eight bit fields of frame\_rate show the frame rate of the video corresponding to video\_stream\_PID in ProgramInfo(), as shown in <u>drawing 57</u>. Eight bit fields of display\_aspect\_ratio show the display aspect ratio of the video corresponding to video\_stream\_PID in ProgramInfo(), as shown in drawing 58.

[0229] <u>Drawing 59</u> is drawing showing the syntax of AudioCodingInfo in the syntax of Programinfo shown in <u>drawing 54</u>. For explaining the syntax of AudioCodingInfo shown in <u>drawing 59</u>, eight bit fields of audio\_coding show the coding approach of the audio corresponding to audio\_stream\_PID in ProgramInfo(), as shown at <u>drawing 60</u>.

[0230] Eight bit fields of audio\_component\_type show the component type of the audio corresponding to audio\_stream\_PID in ProgramInfo(), as shown in <a href="mailto:drawing 61">drawing 61</a>. Eight bit fields of sampling\_frequency show the sampling frequency of the audio corresponding to audio\_stream\_PID in ProgramInfo(), as shown in drawing 62.

[0231] Next, CPI in the syntax of zzzzz.clip shown in <u>drawing 45</u> (Characteristic Point Information) is explained. Since the hour entry in AV stream and the address in the file are associated, there is CPI. There are two types of CPI(s) and they are EP\_map and TU\_map. As shown in <u>drawing 63</u>, when CPI\_type in CPI() is EP\_map type, the CPI() contains EP\_map. As

shown in <u>drawing 64</u>, when CPI\_type in CPI() is TU\_map type, the CPI() contains TU\_map. One AV stream has one EP\_map or one TU\_map. When AV stream is a SESF transport stream, Clip corresponding to it must have EP\_map.

[0232] <u>Drawing 65</u> is drawing showing the syntax of CPI. They are four character alphabetic characters in which version\_number shows the version number of this CPI() for explaining the syntax of CPI shown in <u>drawing 65</u>. version\_number must be encoded with "0045" according to ISO 646. length is a 32-bit unsigned integer which shows the byte count of CPI() from immediately after this length field to the last of CPI(). As shown in <u>drawing 66</u>, CPI\_type is a 1-bit flag and expresses the type of CPI of Clip.

[0233] Next, EP\_map in the syntax of CPI shown in <u>drawing 65</u> is explained. There are two types of EP\_map and they are EP\_map for video streams, and EP\_map for audio streams. EP\_map\_type in EP\_map distinguishes the type of EP\_map. When Clip contains one or more video streams, EP\_map for video streams must be used. When Clip contains one or more audio streams excluding a video stream, EP\_map for audio streams must be used.

[0234] EP\_map for video streams is explained with reference to <u>drawing 67</u>. EP\_map for video streams has data called stream\_PID, PTS\_EP\_start, and RSPN\_EP\_start. stream\_PID shows PID of transport Paquette who transmits a video stream. PTS\_EP\_start shows PTS of the access unit which begins from the sequence header of a video stream. RSPN\_EP\_start shows the address of the source packet containing the 1st byte of the access unit referred to by PTS\_EP\_start in AV stream.

[0235] The sub table called EP\_map\_for\_one\_stream\_PID() is made for every video stream transmitted by transport Paquette with the same PID. When two or more video streams exist in Clip, EP\_map may also contain two or more EP\_map\_for\_one\_stream\_PID().

[0236] EP\_map for audio streams has data called stream\_PID, PTS\_EP\_start, and RSPN\_EP\_start. stream\_PID shows PID of transport Paquette who transmits an audio stream. PTS\_EP\_start shows PTS of the access unit of an audio stream. RSPN\_EP\_start shows the address of the source packet containing the 1st byte of the access unit referred to by PTS\_EP\_start in AV

stream.

[0237] The sub table called EP\_map\_for\_one\_stream\_PID() is made for every audio stream transmitted by transport Paquette with the same PID. When two or more audio streams exist in Clip, EP\_map may also contain two or more EP\_map\_for\_one\_stream\_PID().

[0238] One EP\_map\_for\_one\_stream\_PID() is made by explaining the relation between EP\_map and STC\_Info regardless of the break point of STC at one table. By comparing the value of RSPN\_STC\_start defined in the value of RSPN\_EP\_start and STC\_Info() shows the boundary of the data of EP\_map belonging to each STC\_sequence (see <a href="mailto:drawing-68">drawing-68</a>). - EP\_map must have one EP\_map\_for\_one\_stream\_PID to the range of the continuous stream transmitted by the same PID. When shown in <a href="mailto:drawing-69">drawing-69</a>, although program#1 and program#3 have the same video PID, since the data range is not continuing, they must have EP\_map\_for\_one\_stream\_PID for every program.

[0239] <u>Drawing 70</u> is drawing showing the syntax of EP\_map. For explaining the syntax of EP\_map shown in <u>drawing 70</u>, EP\_type is the 4-bit field, and as shown at <u>drawing 71</u>, it shows the entry point type of EP\_map. EP\_type shows the semantics of the data field following this field. EP\_type must be set to 0 ('video') when Clip contains one or more video streams. Or EP\_type must be set to 1 ('audio') when Clip contains one or more audio streams excluding a video stream.

[0240] The 16-bit field of number\_of\_stream\_PIDs shows the loop count of for-loop which has number\_of\_stream\_PIDs in EP\_map() in a variable. The 16-bit field of stream\_PID (k) shows PID of transport Paquette who transmits the k-th elementary stream (video or audio stream) referred to by EP\_map\_for\_one\_stream\_PID (num\_EP\_entries (k)). case EP\_type is equal to

0 ('video') -- the elementary stream -- a video stream -- kicking does not become impossible Moreover, when EP\_type is equal to 1 ('audio'), the elementary stream must be an audio stream.

[0241] The 16-bit field of num\_EP\_entries (k) shows num\_EP\_entries (k) referred to by EP\_map\_for\_one\_stream\_PID (num\_EP\_entries (k)). EP\_map\_for\_one\_stream\_PID\_Start\_address (k): This 32-bit field shows the

relative byte position from which EP\_map\_for\_one\_stream\_PID (num\_EP\_entries (k)) begins in EP\_map(). This value is shown by the magnitude from the 1st byte of EP\_map().

[0242] padding\_word must be inserted according to the syntax of EP\_map(). X and Y must be the positive integers of zero or arbitration. Each padding WORD may take any value.

[0243] Drawing 72 is drawing showing the syntax of

EP\_map\_for\_one\_stream\_PID. The semantics of the 32-bit field of PTS\_EP\_start changes with EP\_type(s) defined in EP\_map() to explain the syntax of EP\_map\_for\_one\_stream\_PID shown in drawing 72. When EP\_type is equal to 0 ('video'), this field has 32 bits of high orders of PTS of the 33-bit precision of the access unit which starts in the sequence header of a video stream. When EP\_type is equal to 1 ('audio'), this field has 32 bits of high orders of PTS of the 33-bit precision of the access unit of an audio stream. [0244] The semantics of the 32-bit field of RSPN\_EP\_start changes with EP\_type defined in EP\_map(). When EP\_type is equal to 0 ('video'), this field shows the relative address of the source packet containing the 1st byte of the sequence header of the access unit referred to by PTS\_EP\_start in AV stream. Or when EP\_type is equal to 1 ('audio'), this field shows the relative address of the source packet containing the first byte of the audio frame of the access unit referred to by PTS\_EP\_start in AV stream.

[0245] RSPN\_EP\_start is magnitude which makes a source packet number a unit, and counts the value of offset\_SPN defined in ClipInfo() from the source packet of the beginning of AV stream file as initial value. The absolute address in the inside of the AV stream file is computed by SPN\_xxx = RSPN\_xxx-offset\_SPN. The value of RSPN\_EP\_start must appear in ascending order in for-loop of syntax.

[0246] Next, TU\_map is explained with reference to <u>drawing 73</u>. TU\_map makes one time-axis based on the arrival timer clock (clock of the arrival time base) of a source packet. The time-axis is called TU\_map\_time\_axis. The zero of TU\_map\_time\_axis is shown by offset\_time in TU\_map().

TU\_map\_time\_axis is divided into a fixed unit from offset\_time. The unit is called time\_unit.

[0247] In each time\_unit in AV stream, the address on AV stream file of the source packet of the first perfect form is stored in TU\_map. These addresses are called RSPN\_time\_unit\_start. It sets on TU\_map\_time\_axis and is k. The time of day when time\_unit of eye watch (k>=0) starts is called TU\_start\_time (k). This value is computed based on a degree type.

TU\_start\_time (k) = offset\_time+k\*time\_unit\_sizeTU\_start\_time (k) has the precision of 45kHz.

[0248] <u>Drawing 74</u> is drawing showing the syntax of TU\_map. The field of the 32-bit length of offset\_time gives the offset time to TU\_map\_time\_axis for explaining the syntax of TU\_map shown in <u>drawing 74</u>. This value shows the offset time of day to time\_unit of the beginning in Clip. offset\_time is magnitude which makes a unit the 45kHz clock drawn from the arrival timer clock of 27MHz precision. offset\_time must be set to zero when AV stream is recorded as new Clip.

[0249] 32 bit fields of time\_unit\_size give the magnitude of time\_unit, and it is magnitude which makes a unit the 45kHz clock drawn from the arrival timer clock of 27MHz precision. time\_unit\_size is good to make it 1 or less (time\_unit\_size<=45000) second. 32 bit fields of number\_of\_time\_unit\_entries show the number of entries of time\_unit currently stored in TU\_map(). [0250] 32 bit fields of RSPN\_time\_unit\_start show the relative address of the location which each time\_unit starts in AV stream. RSPN\_time\_unit\_start is magnitude which makes a source packet number a unit, and counts the value of offset\_SPN defined in ClipInfo() from the source packet of the beginning of an AV stream file as initial value. The absolute address in the inside of the AV stream file is computed by SPN\_xxx = RSPN\_xxx-offset\_SPN. The value of RSPN\_time\_unit\_start must appear in ascending order in for-loop of syntax. (k+1) When anything does not have a source packet into time\_unit of eye watch, RSPN\_time\_unit\_start.

[0251] ClipMark in the syntax of zzzzz.clip shown in <u>drawing 45</u> is explained. ClipMark is the mark information about a clip and is stored into ClipMark. This mark is not set by the recorder (record regenerative apparatus 1), and is not set by the user.

[0252] <u>Drawing 75</u> is drawing showing the syntax of ClipMark. They are four character alphabetic characters in which version\_number shows the version number of this ClipMark() for explaining the syntax of ClipMark shown in <u>drawing 75</u>. version\_number must be encoded with "0045" according to ISO 646.

[0253] length is a 32-bit unsigned integer which shows the byte count of ClipMark() from immediately after this length field to the last of ClipMark(). number\_of\_Clip\_marks, the 16-bit unsigned integer which shows the number of the mark currently stored in ClipMark. number\_of\_Clip\_marks You may be 0. mark\_type is the 8-bit field which shows the type of a mark, and is encoded according to the table shown in drawing 76.

[0254] mark\_time\_stamp is 32 bit fields and stores the time stump in which the point with which the mark was specified is shown. The semantics of mark\_time\_stamp changes with CPI\_type in PlayList(), as shown in <u>drawing</u> 77.

[0255] When, as for STC\_sequence\_id, CPI\_type in CPI() shows EP\_map type, this 8-bit field shows STC\_sequence\_id of the STC continuation section on which mark\_time\_stamp is put. When CPI\_type in CPI() shows TU\_map type, this 8-bit field has no semantics, but is set to zero. The 8-bit field of character\_set shows the coding approach of the character alphabetic character encoded by the mark\_name field. The coding approach corresponds to the value shown in drawing 19.

[0256] Eight bit fields of name\_length show the cutting tool length of the mark name shown in the Mark\_name field. The field of mark\_name shows the name of a mark. The byte count of the left in this field to a name\_length number is an effective character alphabetic character, and it shows the name of a mark. In the mark\_name field, as for the value after these effective characters alphabetic character, what kind of value may be in close.

[0257] The field of ref\_thumbnail\_index shows the information on the thumbnail image added to a mark. In the case of the value whose ref\_thumbnail\_index field is not 0xFFFF, the thumbnail image is added to the mark and the thumbnail image is stored in the mark.thmb file. The image is referred to using the value of ref\_thumbnail\_index in a mark.thmb file. the

ref\_thumbnail\_index field -- 0xFFFF it is -- a case -- the mark -- a thumbnail image -- adding -- having -- \*\*\*\* .

[0258] Drawing 78 is drawing showing other syntax of ClipMark replaced with drawing 75, and drawing 79 shows the example of the table of mark\_type which can be set in that case and which replaces drawing 76. the time of mark\_type showing the value of 0xFF from 0xC0, as for reserved\_for\_maker\_ID -- the -- It is the 16-bit field which shows the manufacturer ID of the manufacturer who defines mark\_type. A DVR format licenser specifies Manufacturer ID. mark\_entry() is information which shows the point specified as the marking point, and the detail of the syntax is mentioned later. representative\_picture\_entry() is information which shows the point of the image representing the mark shown by mark\_entry(), and the detail of the syntax is mentioned later.

[0259] When a user reproduces AV stream, ClipMark is used in order to enable it to search the content visually. A DVR player uses GUI (graphical user interface), and shows a user the information on ClipMark. It is better to show the picture which representative\_picture\_entry() shows rather than the picture which mark\_entry() shows, in order to display the information on ClipMark visually.

[0260] The example of mark\_entry() and representative\_picture\_entry() is shown in drawing 80. For example, suppose that the program name (title) of the program is displayed after a certain program begins, and carrying out for a while (after several seconds). When making ClipMark, mark\_entry() is put on the initiation point of the program, and you may make it put representative\_picture\_entry() on the point with which the program name (title) of the program is displayed.

[0261] If a DVR player displays the image of representative\_picture\_entry on GUI and a user specifies the image, a DVR player will start playback from the point with which mark\_entry was placed.

[0262] mark\_entry() It reaches. The syntax of representative\_picture\_entry() is shown in drawing 81.

[0263] mark\_time\_stamp is 32 bit fields, in mark\_entry(), the time stump in which the point with which the mark was specified is shown is stored, and it

stores the time stump in which the point of the image representing the mark shown by mark\_entry() is shown in representative\_picture\_entry(). [0264] Next, mark\_entry() in the case of using the information on the address base rather than using the information on the time stump base by PTS, in order to specify ClipMark The example of the syntax of representative\_picture\_entry() is shown in drawing 82. [0265] In RSPN\_ref\_EP\_start and mark\_entry(), the relative address of the source packet which shows the entry point of the stream for decoding the picture of a marking point in AV stream is shown. Moreover, in representative\_picture\_entry(), the relative address of the source packet which shows the entry point of the stream for decoding the picture representing the mark shown by mark\_entry() is shown. The value of

value of PTS\_EP\_start corresponding to the RSPN\_EP\_start must be value nearest than PTS of the picture of a marking point among the past in EP\_map. [0266] offset\_num\_pictures is the 32-bit field and shows the number of pictures of the offset to a picture shown with a marking point by the display order from the picture referred to by RSPN\_ref\_EP\_start. This number is counted from zero. In the case of the example of drawing 83, offset\_num\_pictures is set to 6.

RSPN\_ref\_EP\_start must be stored as RSPN\_EP\_start in EP\_map, and the

[0267] Next, mark\_entry() in the case of using the information on the address base, in order to specify ClipMark Another example of the syntax of representative\_picture\_entry() is shown in drawing 84.

[0268] In mark\_entry(), RSPN\_mark\_point shows the relative address of the source packet which contains the 1st byte of the access unit which the mark refers to in AV stream. Moreover, in representative\_picture\_entry(), the relative address of the source packet containing the 1st byte of the coding picture representing the mark shown by mark\_entry() is shown.

[0269] RSPN\_mark\_point is magnitude which makes a source packet number a unit, and counts the value of offset\_SPN defined in Clip Information file from the source packet of the beginning of AV stream file as initial value.

[0270] The relation between ClipMark and EP\_map is explained using drawing 85. In the case of this example, EP\_map specifies I0, I1, and In as

the address of an entry point, and presupposes that I picture which follows a sequence header from these addresses has begun. What is necessary is to read data from I1 which is the nearest entry point before the address of M1, and just to start, in order to be able to decode the picture started from the source packet, when ClipMark specifies M1 as the address of a certain mark. [0271] Since MakersPrivateData was already explained with reference to drawing 22, the explanation is omitted.

[0272] Next, a thumbnail information (Thumbnail Information) is explained. A thumbnail image is stored in a menu.thmb file or a mark.thmb file. These files are the same syntax structures and have only one Thumbnail(). A menu.thmb file stores a menu thumbnail image, i.e., the image representing Volume, and the image representing each PlayList. All menu thumbnails are stored only in one menu.thmb file.

[0273] A mark.thmb file stores the picture showing a mark thumbnail image, i.e., a marking point. All the mark thumbnails to all PlayList(s) and Clip(s) are stored only in one mark.thmb file. Since a thumbnail is added frequently and deleted, add operation and actuation of partial deletion must be able to be easily performed at a high speed. Thumbnail() has the block structure for this reason. The data of an image are divided into some parts and each part is stored in one tn\_block. One image data is stored in tn\_block which \*\*\*\*\*\*(ed). tn\_block which is not used may exist in the train of tn\_block. The cutting tool length of one thumbnail image is adjustable.

[0274] <u>Drawing 86</u> is drawing showing the syntax of menu.thmb and mark.thmb, and <u>drawing 87</u> is drawing showing the syntax of Thumbnail in the syntax of menu.thmb shown in <u>drawing 86</u>, and mark.thmb. They are four character alphabetic characters in which version\_number shows the version number of this Thumbnail() for explaining the syntax of Thumbnail shown in <u>drawing 87</u>. version\_number must be encoded with "0045" according to ISO 646.

[0275] length is a 32-bit unsigned integer which shows the byte count of MakersPrivateData() from immediately after this length field to the last of Thumbnail(). tn\_blocks\_start\_address is a 32-bit unsigned integer which shows the head byte address of the first tn\_block by making the relative byte

count from the cutting tool of the head of Thumbnail() into a unit. A relative byte count is counted from zero. number\_of\_thumbnails is a 16-bit unsigned integer which gives the number of entries of the thumbnail image contained in Thumbnail().

[0276] tn\_block\_size is a 16-bit unsigned integer which gives the magnitude of one tn\_block by making 1024 bytes into a unit. For example, if it becomes tn\_block\_size=1, it shows that the magnitude of one tn\_block is 1024 bytes. number\_of\_tn\_blocks is a 116-bit unsigned integer showing the number of entries of tn\_block in this Thumbnail(). thumbnail\_index is a 16-bit unsigned integer showing the index number of the thumbnail image expressed with the thumbnail information on the "for" loop batch which begins from this thumbnail\_index field. thumbnail\_index Don't carry out and don't use the value of 0xFFFF. thumbnail\_index Refer to for ref\_thumbnail\_index in UIAppInfoVolume(), UIAppInfoPlayList(), PlayListMark(), and ClipMark(). [0277] thumbnail\_picture\_format is a 8-bit unsigned integer showing a picture format of a thumbnail image, and takes a value as shown in drawing 88. DCF and PNG in a table are allowed only within "menu.thmb." A mark thumbnail must take value"0x00" (MPEG-2 Video I-picture).

[0278] picture\_data\_size is a 32-bit unsigned integer which shows the cutting tool length of a thumbnail image per cutting tool. start\_tn\_block\_number is a 16-bit unsigned integer showing the tn\_block number of tn\_block from which the data of a thumbnail image begin. The head of thumbnail image data must be in agreement with the head of tb\_block. A tn\_block number begins from 0 and is related to the value of the variable k in the "for" loop of tn\_block. [0279] x\_picture\_length is a 16-bit unsigned integer showing the horizontal number of pixels of the frame picture frame of a thumbnail image.

y\_picture\_length is a 16-bit unsigned integer showing the number of pixels of the perpendicular direction of the frame picture frame of a thumbnail image. tn\_block, It is the field in which a thumbnail image is stored. All tn\_block in Thumbnail() is the same sizes (fixed length), and the magnitude is defined by tn\_block\_size.

[0280] <u>Drawing 89</u> is drawing which meant typically how thumbnail image data would be stored in tn\_block. Like <u>drawing 89</u>, each thumbnail image data

begins from the head of tn\_block, and, in the case of the magnitude exceeding 1 tn\_block, it is stored using continuous following tn\_block. By doing in this way, the picture data which is variable length becomes possible [managing as fixed-length data], and can respond now by simple processing to edit called deletion.

[0281] Next, AV stream file is explained. AV stream file is stored in an "M2TS" directory ( drawing 14 ). There are two types of AV stream files, and they are a Clip AV stream and a Bridge-Clip AV stream file. It must be the structure of a DVR MPEG-2 transport stream file where both AV streams are defined henceforth [ this ].

[0282] First, DVR MPEG-2 A transport stream is explained. The structure of a DVR MPEG-2 transport stream is shown in drawing 90. AV stream file has the structure of a DVR MPEG 2 transport stream. A DVR MPEG 2 transport stream consists of Aligned unit of an integer individual, the magnitude of Alignedunit -- 6144 Cutting tool (2048\*3 cutting tool) it is. Aligned unit begins from the 1st byte of a source packet. A source packet is 192-byte length. One source packet consists of TP\_extra\_header and transport Paquette.

TP\_extra\_header is 4-byte length and transport Paquette is 188-byte length. [0283] One Aligned unit consists of 32 source packets. Aligned unit of the last in a DVR MPEG 2 transport stream also consists of 32 source packets.

Therefore, termination of the DVR MPEG 2 transport stream is carried out on the boundary of Aligned unit. When the number of transport Paquette of the input transport stream recorded on a disk is not a multiple of 32, a source packet with Nur Paquette (transport Paquette of PID=0x1FFF) must be used for the last Aligned unit. A file system must not add excessive information to a DVR MPEG 2 transport stream.

[0284] The recorder model of a DVR MPEG-2 transport stream is shown in drawing 91. The recorder shown in drawing 91 is a model on the concept for specifying a recording process. A DVR MPEG-2 transport stream follows this model.

[0285] The input timing of an MPEG-2 transport stream is explained. An input MPEG 2 transport stream is a full transport stream or a partialness transport stream. The MPEG 2 transport stream inputted must follow ISO/IEC 13818-1

or ISO/IEC 13818-9. The i-th cutting tool of an MPEG 2 transport stream is simultaneously inputted into T-STD (Transport stream system target decoder specified by ISO/IEC 13818-1)51, and sow spa KETTAIZA (sourse packetizer) 54 at time-of-day t (i). Rpk is the instant-maximum of transport Paquette's input rate.

[0286] PLL52 generates 27MHz of frequencies of a 27MHz clock. The frequency of a 27MHz clock is locked by the value of PCR (Program Clock Reference) of an MPEG-2 transport stream. The arrival timer clock counter (arrival time clock counter) 53 is a binary counter which counts a pulse with a frequency of 27MHz. Arrival\_time\_clock (i) is the counted value of arrival time clockcounter53 in time-of-day t (i).

[0287] source packetizer54 adds TP\_extra\_header to all transport Paquette, and makes a source packet. Arrival\_time\_stamp expresses the time of day when transport Paquette's 1st byte arrives to both T-STD51 and sow spa KETTAIZA 54. Arrival\_time\_stamp (k) is the sampled value of Arrival\_time\_clock (k), as shown in a degree type, and k shows transport Paquette's 1st byte here.

arrival\_time\_stamp (k) = arrival\_time\_clock(k) % 230[0288] When two time intervals of transport Paquette inputted continuously become 230 / more than 27 million second (about 40 seconds), the two difference of transport Paquette's arrival\_time\_stamp should be set as it has been 230 / 27 million seconds. It has the recorder, when becoming such.

[0289] The smoothing buffer (smoothing buffer) 55 carries out smoothing of the bit rate of an input transport stream. Don't overflow the smoothing buffer 55. Rmax is the output bit rate of the source packet from the smoothing buffer 55 in case the smoothing buffer 55 is not empty. When the smoothing buffer 55 is empty, the output bit rate from the smoothing buffer 55 is zero.

[0290] Next, the parameter of the recorder model of a DVR MPEG-2 transport stream is explained. The value of Rmax is given by TS\_recording\_rate defined in ClipInfo() corresponding to AV stream file. This value is computed by the degree type.

The value of Rmax = TS\_recording\_rate \* 192/188 TS\_recording\_rate is magnitude which makes bytes/second a unit.

[0291] When an input transport stream is a SESF transport stream, Rpk must be equal to TS\_recording\_rate defined in ClipInfo() corresponding to AV stream file. When an input transport stream is not a SESF transport stream, refer to the value defined in a descriptor, for example, maximum\_bitrate\_descriptor, partial\_transport\_stream\_descriptor, etc. of

[0292] When an input transport stream is a SESF transport stream, the magnitude (smoothing buffer size) of the smoothing buffer 55 is zero. When an input transport stream is not a SESF transport stream, refer to the value defined in the descriptor of MPEG-2 transport stream, for example, smoothing\_buffer\_descriptor, short\_smoothing\_buffer\_descriptor, partial\_transport\_stream\_descriptor, etc. for the magnitude of the smoothing buffer 55.

MPEG-2 transport stream for this value.

[0293] A record machine (recorder) and the record regenerative apparatus 1 (player) must prepare the buffer of sufficient size. default buffer size -- 1536 bytes it is .

[0294] Next, the player model of a DVR MPEG-2 transport stream is explained. Drawing 92 is drawing showing the player model of a DVR MPEG-, 2 transport stream. This is a model on the concept for specifying reconstructive processing. A DVR MPEG-2 transport stream follows this model.

[0295] 27 MHz X-tal (crystal oscillator)61 generates the frequency of 27MHz. The error range of a 27MHz frequency must be +/-30 ppm (27 million+/-810 Hz). arrival time clock counter62 is a binary counter which counts a pulse with a frequency of 27MHz. arrival\_time\_clock (i) is the counted value of arrival time clock counter62 in time-of-day t (i).

[0296] In smoothing buffer64, Rmax is the input bit rate of the source packet to the smoothing buffer 64 in case the smoothing buffer 64 is not full. When the smoothing buffer 64 is full, the input bit rate to the smoothing buffer 64 is zero.

[0297] When arrival\_time\_stamp of the present source packet is equal to the value which is 30 bits of LSB of arrival\_time\_clock (i) for explaining the output timing of an MPEG-2 transport stream, transport Paquette, the source packet,

is lured from the smoothing buffer 64. Rpk is the instant-maximum of a transport packet rate. Don't carry out the underflow of the smoothing buffer 64. [0298] About the parameter of the player model of a DVR MPEG-2 transport stream, it is the same as that of the parameter of the recorder model of a DVR MPEG-2 transport stream mentioned above.

[0299] <u>Drawing 93</u> is drawing showing the syntax of Source packet. transport\_packet() is MPEG-2 transport Paquette specified by ISO/IEC 13818-

1. The syntax of TP\_Extra\_header in the syntax of Source packet shown in drawing 93 is shown in drawing 94. It is the integer as which copy\_permission\_indicator expresses a copy limit of transport Paquette's pay load for explaining the syntax of TP\_Extra\_header shown in drawing 94. A copy limit can be set to copy free, no more copy, copy once, or copy prohibited. Drawing 95 shows the value of copy\_permission\_indicator, and the relation in the mode specified by them.

[0300] copy\_permission\_indicator is added to all transport Paquette. The value of copy\_permission\_indicator may be related with the value of EMI in IEEE1394 isochronouspacket header (Encryption Mode Indicator) when recording an input transport stream using an IEEE1394 digital interface. The value of copy\_permission\_indicator may be related with the value of CCI embedded into transport Paquette, when recording an input transport stream without using an IEEE1394 digital interface. The value of copy\_permission\_indicator may be related with the value of CGMS-A of an analog signal when carrying out self encoding of the analog signal input. [0301] arrival\_time\_stamp is degree type arrival\_time\_stamp (k). In = arrival\_time\_clock(k) % 230, it is an integral value with the value specified by arrival\_time\_stamp.

[0302] A Clip AV stream must have [ defining a Clip AV stream and ] the structure of a DVR MPEG-2 transport stream where a definition which was mentioned above is carried out. arrival\_time\_clock (i) must increase continuously in a Clip AV stream. Even if the break point of system time base (STC base) exists in a Clip AV stream, arrival\_time\_clock (i) of the Clip AV stream must increase continuously.

[0303] The maximum of the difference of the initiation in a Clip AV stream and

arrival\_time\_clock between termination (i) must be 26 hours. This limit guarantees that PTS (Presentation Time Stamp) of the same value never appears in a Clip AV stream, when the break point of system time base (STC base) does not exist in an MPEG 2 transport stream. MPEG 2 systems specification has specified the wrap around period of PTS as 233 / 90000 second (about 26.5 hours).

[0304] A Bridge-Clip AV stream must have [ defining a Bridge-Clip AV stream and ] the structure of a DVR MPEG-2 transport stream where a definition which was mentioned above is carried out. A Bridge-Clip AV stream must contain the break point of one arrival time base. The transport stream before and behind the break point of arrival time base must follow DVR-STD which must follow a limit of coding mentioned later and is mentioned later.

[0305] In the gestalt of this operation, the video between PlayItem(s) in edit and seamless connection of an audio are supported. Making between PlayItem seamless connection guarantees "continuation supply of data", and "seamless decode processing" to a player/recorder. "Continuation supply of data" is being able to guarantee a file system supplying data with a required bit rate so that a decoder's may not be made to cause the underflow of a buffer. The real time nature of data is guaranteed, and data are stored in the block unit which sufficient magnitude followed so that data can be read from a disk.

[0306] "Seamless decode processing" is that a player can display the audio video data recorded on the disk, without making the playback output of a decoder start a pause and a gap.

[0307] AV stream which PlayItem by which seamless connection is made refers to is explained. It can judge whether connection of PlayItem to precede and the present PlayItem is guaranteed to indicate by seamless from the connection\_condition field defined in the present PlayItem. The seamless connection between PlayItem(s) has the approach of using Bridge-Clip, and the approach which is not used.

[0308] <u>Drawing 96</u> shows the relation between PlayItem preceded in the case of using Bridge-Clip, and the present PlayItem. In <u>drawing 96</u>, the stream data which a player reads give a shadow and are shown. TS1 shown in

drawing 96 consists of the stream data which were able to attach the shadow of Clip1 (Clip AV stream), and the stream data which were able to attach the shadow before RSPN\_arrival\_time\_discontinuity of Bridge-Clip.

[0309] The stream data which were able to attach the shadow of Clip1 of TS1 are stream data from the address of a stream required in order to decode the presentation unit corresponding to IN\_time (illustrated by IN\_time1 in drawing 96) of PlayItem to precede to the source packet referred to by RSPN\_exit\_from\_previous\_Clip. The stream data which were able to attach the shadow before RSPN\_arrival\_time\_discontinuity of Bridge-Clip contained in TS1 are stream data from the source packet of the beginning of Bridge-Clip to the source packet in front of the source packet referred to by RSPN\_arrival\_time\_discontinuity.

[0310] Moreover, TS2 in drawing 96 consists of the stream data which were able to attach the shadow of Clip2 (Clip AV stream), and the stream data which were able to attach the shadow after RSPN\_arrival\_time\_discontinuity of Bridge-Clip. The stream data which were able to attach the shadow after RSPN\_arrival\_time\_discontinuity of Bridge-Clip contained in TS2 are stream data from the source packet referred to by RSPN\_arrival\_time\_discontinuity to the source packet of the last of Bridge-Clip. The stream data which were able to attach the shadow of Clip2 of TS2 are stream data to the address of a stream required in order to decode the presentation unit corresponding to OUT\_time (illustrated by OUT\_time2 in drawing 96 ) of the present PlayItem from the source packet referred to by RSPN\_enter\_to\_current\_Clip. [0311] Drawing 97 shows the relation between PlayItem preceded when not using Bridge-Clip, and the present PlayItem. In this case, the stream data which a player reads give a shadow and are shown. TS1 in drawing 97 consists of the stream data which were able to attach the shadow of Clip1 (Clip AV stream). The stream data which were able to attach the shadow of Clip1 of TS1 begin from the address of a stream required in order to decode the presentation unit corresponding to IN\_time (illustrated by IN\_time1 in drawing 97) of PlayItem to precede, and are data to the source packet of the last of Clip1. Moreover, TS2 in drawing 97 consists of the stream data which were able to attach the shadow of Clip2 (Clip AV stream).

[0312] The stream data which were able to attach the shadow of Clip2 of TS2 are stream data to the address of a stream required in order to begin from the source packet of the beginning of Clip2 and to decode the presentation unit corresponding to OUT\_time (illustrated by OUT\_time2 in drawing 97) of the present PlayItem.

[0313] In drawing 96 and drawing 97, TS1 and T2 are the streams which the source packet followed. Next, a stream convention of TS1 and TS2 and the connection conditions between them are considered. First, the coding limit for seamless connection is considered. As a limit of the coding structure of a transport stream, the number of the programs included in TS1 and TS2 must be 1 first. The number of the video streams contained in TS1 and TS2 must be 1. The number of the audio streams contained in TS1 and TS2 must be two or less. The number of the audio streams contained in TS1 and TS2 must be equal. In TS1 and/or TS2, the elementary streams or private streams other than the above may be contained.

[0314] A limit of a video bit stream is explained. <u>Drawing 98</u> is drawing showing the example of the seamless connection shown by the display order of a picture. In order to be able to display a video stream seamlessly in a node, the unnecessary picture displayed before IN\_time2 (IN\_time of Clip2) the OUT\_time1 (OUT\_time of Clip1) back must be removed by the process which re-encodes the partial stream of Clip near a node.

[0315] The example which makes seamless connection using BridgeSequence when shown in <u>drawing 98</u> is shown in <u>drawing 99</u>. The video stream of Bridge-Clip before RSPN\_arrival\_time\_discontinuity consists of the coding video stream to the picture corresponding to OUT\_time1 of Clip1 of <u>drawing 98</u>. And it connects with the video stream of Clip1 to precede, and the video stream is re-encoded so that it may become the elementary stream which followed MPEG 2 specification by one continuation.

[0316] Similarly, the video stream of Bridge-Clip after

RSPN\_arrival\_time\_discontinuity consists of the coding video stream after the picture corresponding to IN\_time2 of Clip2 of <u>drawing 98</u>. And decoding initiation can be carried out correctly and it connects with the video stream of Clip2 following this, and the video stream is re-encoded so that it may become

the elementary stream which followed MPEG 2 specification by one continuation. In order to make Bridge-Clip, generally, the picture of several sheets must be re-encoded and the other picture can be copied from Clip of an original copy.

[0317] The example which makes seamless connection without using BridgeSequence in the case of the example shown in drawing 98 is shown in drawing 100. The video stream of Clip1 consists of the coding video stream to the picture corresponding to OUT\_time1 of drawing 98, and it is reencoded so that it may become the elementary stream which followed MPEG 2 specification by one continuation. Similarly, the video stream of Clip2 consists of the coding video stream after the picture corresponding to IN\_time2 of Clip2 of drawing 98, and it is re-encoded so that it may become the elementary stream which followed MPEG 2 specification by one continuation.

[0318] The frame rate of the video stream of TS1 and TS2 must be equal to explaining a coding limit of a video stream first. Termination of the video stream of TS1 must be carried out by sequence\_end\_code. The video stream of TS2 must be started by Sequence Header, GOP Header, and I-picture. the video stream of TS2 -- closed one -- it must start by GOP.

[0319] The video presentation unit (a frame or field) defined in a bit stream must be continuation on both sides of a node. There must not be no gap of a frame or the field in a node. In a node, the field sequence of a top-bottom product must be continuation. In encoding which uses 3-2 PURUDAUN, it is "top\_field\_first". It reaches. In order to rewrite a "repeat\_first\_field" flag or to prevent generating of a field gap, you may make it re-encode locally. [0320] The sampling frequency of the audio of TS1 and TS2 must be the same as explaining a coding limit of an audio bit stream. The coding approach (example . MPEG1 layer 2, AC-3, SESF LPCM, AAC) of the audio of TS1 and TS2 must be the same.

[0321] Next, the audio frame of the last of the audio stream of TS1 must contain the audio sample with display time of day equal at the time of display termination of the display picture of the last of TS1 in explaining a coding limit of an MPEG-2 transport stream. The audio frame of the beginning of the

audio stream of TS2 must contain the audio sample with display time of day equal at the time of display initiation of the display picture of the beginning of TS2.

[0322] In a node, a gap must not be in the sequence of an audio presentation unit. As shown in drawing 101, there may be overlap defined by the die length of the audio presentation unit of under 2 audio frame section. The first Paquette who transmits the elementary stream of TS2 must be a video packet. The transport stream in a node must follow DVR-STD mentioned later.

[0323] TS1 and TS2 must not contain the break point of arrival time base in explaining a limit of Clip and Bridge-Clip in each.

[0324] The following limits are applied only when using Bridge-Clip. Only in the node of the source packet of the last of TS1, and the source packet of the beginning of TS2, a Bridge-ClipAV stream has the break point of only one arrival time base. RSPN\_arrival\_time\_discontinuity defined in ClipInfo() must show the address of the break point, and it must show the address which refers to the source packet of the beginning of TS2.

[0325] Any source packet in Clip1 is sufficient as the source packet referred to by RSPN\_exit\_from\_previous\_Clip defined in BridgeSequenceInfo(). It does not need to be the boundary of Aligned unit. Any source packet in Clip2 is sufficient as the source packet referred to by RSPN\_enter\_to\_current\_Clip defined in BridgeSequenceInfo(). It does not need to be the boundary of Aligned unit.

[0326] OUT\_time (OUT\_time1 shown in drawing 96 and drawing 97) of PlayItem preceded for explaining a limit of PlayItem must show the display end time of the video presentation unit of the last of TS1. IN\_time (IN\_time2 shown in F drawing 96 and drawing 97) of the present PlayItem must show the display start time of the video presentation unit of the beginning of TS2. [0327] Seamless connection must be made by explaining a limit of the data allocation in the case of using Bridge-Clip with reference to drawing 102 so that continuation supply of data may be guaranteed by the file system. This must be performed by arranging the Bridge-Clip AV stream connected to Clip1 (ClipAV stream file) and Clip2 (Clip AV stream file) so that a data allocation convention may be fulfilled.

[0328] RSPN\_exit\_from\_previous\_Clip must be chosen as the stream part of Clip1 (Clip AV stream file) before RSPN\_exit\_from\_previous\_Clip is arranged to the continuation field more than half fragmentation. The data length of a Bridge-Clip AV stream must be chosen so that it may be arranged to the continuation field more than half fragmentation. RSPN\_enter\_to\_current\_Clip must be chosen as the stream part of Clip2 (Clip AV stream file) after RSPN\_enter\_to\_current\_Clip is arranged to the continuation field more than half fragmentation.

[0329] Seamless connection must be made by explaining a limit of the data allocation in the case of making seamless connection without using Bridge-Clip with reference to drawing 103 so that continuation supply of data may be guaranteed by the file system. This must be performed by arranging the part of the last of Clip1 (Clip AV stream file), and the part of the beginning of Clip2 (Clip AV stream file) so that a data allocation convention may be fulfilled.

[0330] The stream part of the last of Clip1 (Clip AV stream file) must be arranged to the continuation field more than half fragmentation. The stream part of the beginning of Clip2 (Clip AV stream file) must be arranged to the continuation field more than half fragmentation.

[0331] Next, DVR-STD is explained. DVR-STD is a conceptual model for modeling generation of a DVR MPEG 2 transport stream, and decoding in the case of verification. Moreover, DVR-STD is also a conceptual model for modeling generation of AV stream referred to by two PlayItem(s) which were mentioned above, and by which seamless connection was made, and decoding in the case of verification.

[0332] A DVR-STD model is shown in <u>drawing 104</u>. The DVR MPEG-2 transport stream player model is contained in the model shown in <u>drawing 104</u> as a component. The notation approach of of n, TBn, MBn, EBn, TBsys, Bsys, Rxn, Rbxn, Rxsys, Dn, Dsys, and On and Pn (k) is the same as what is defined as T-STD of ISO/IEC 13818-1. That is, it is as follows. n is the index number of an elementary stream. TBn is the transport buffer of the elementary stream n, and is \*\*.

[0333] MBn is the multiplex buffer of the elementary stream n. It exists only about a video stream. EBn is the elementary stream buffer of the elementary

stream n. It exists only about a video stream. TBsys is an input buffer for the system information of the program under decode. Bsys is a main buffer in the system target decoder for the system information of the program under decode. Rxn is a transmission rate by which data are removed from TBn. Rbxn is a transmission rate by which a PES Paquette pay load is removed from MBn. It exists only about a video stream.

[0334] Rxsys is a transmission rate by which data are removed from TBsys. Dn is the decoder of the elementary stream n. Dsys is a decoder about the system information of the program under decode. On is re-ordering buffer of the video stream n. Pn (k) is the k-th presentation unit of the elementary stream n.

[0335] The decoding process of DVR-STD is explained. While reproducing the single DVR MPEG-2 transport stream, the timing which inputs transport Paquette into the buffer of TB1, TBn, or TBsys is determined by arrival\_time\_stamp of a source packet. The convention of buffering actuation of TB1, MB1, EB1, TBn, Bn, TBsys, and Bsys is the same as T-STD specified to ISO/IEC 13818-1. A convention of decode actuation and a display action is the same as T-STD specified to ISO/IEC 13818-1.

[0336] A decoding process while reproducing PlayItem by which seamless connection was made is explained. Here, playback of two AV streams referred to by PlayItem by which seamless connection was made will be explained, and future explanation explains the playback of TS (for example, shown in drawing 96)1, and TS2 mentioned above. TS1 is a stream to precede and TS2 is a current stream.

[0337] <u>Drawing 105</u> shows the timing chart of the input of transport Paquette when moving from a certain AV stream (TS1) to the following AV stream (TS2) seamlessly connected to it, decode, and a display. While moving from predetermined AV stream (TS1) to the following AV stream (TS2) seamlessly connected to it, the time-axis (<u>drawing 105</u> is shown by ATC2) of the arrival time base of TS2 is not the same as the time-axis (<u>drawing 105</u> is shown by ATC1) of the arrival time base of TS1.

[0338] Moreover, the time-axis ( <u>drawing 105</u> is shown by STC2) of the system time base of TS2 is not the same as the time-axis ( drawing 105 is

shown by STC1) of the system time base of TS1. It is required that the display of video should continue seamlessly. Overlap may be shown in the display time of the presentation unit of an audio.

[0339] DVR-STD Input timing is explained. It is TB1 and TBn of DVR-STD until the time amount by time of day T1, i.e., the video packet of the last of TS1, carries out input termination at TB1 of DVR-STD. Or the input timing to the buffer of TBsys is determined by arrival\_time\_stamp of the source packet of TS1.

[0340] Remaining Paquette of TS1 must be inputted into the buffer of TBn of DVR-STD, or TBsys with the bit rate of TS\_recording\_rate (TS1). Here, TS\_recording\_rate (TS1) is the value of TS\_recording\_rate defined in ClipInfo() corresponding to Clip1. The time of day which the cutting tool of the last of TS1 inputs into a buffer is time of day T2. Therefore, arrival\_time\_stamp of a source packet is disregarded in the section from time of day T1 to T2.

[0341] If N1 is made into the byte count of transport Paquette of TS1 following the video packet of the last of TS1, time of day T1 thru/or the time amount DT 1 to T2 will be time amount required in order that 1 byte of N may carry out input termination with the bit rate of TS\_recording\_rate (TS1), and will be computed by the degree type.

deltaT1=T2-T1=N1 / TS\_recording\_rate Both the values of RXn and RXsys change to the value of TS\_recording\_rate (TS1) before time of day (TS1) T1 thru/or T2. The buffering actuation of those other than this rule is the same as T-STD.

[0342] arrival time clock counter is reset by the value of arrival\_time\_stamp of the source packet of the beginning of TS2 in the time of day of T2. TB1 of DVR-STD, and TBn Or the input timing to the buffer of TBsys is determined by arrival\_time\_stamp of the source packet of TS2. RXn and RXsys both change to the value defined in T-STD.

[0343] In addition to the amount of buffers defined by T-STD, an audio decoder and a system decoder need the additional amount of buffers (amount of data for about 1 second) to explain additional audio buffering and system data buffering so that the input data of the section from time of day T1 to T2

can be processed.

[0344] The display of a video presentation unit must let a node pass to explain the presentation timing of video, and it must be continuation without a gap. Here, STC1 considers as the time-axis (in <u>drawing 105</u>, illustrated with STC1) of the system time base of TS1, and STC2 is the time-axis (in <u>drawing 97</u>, illustrated with STC2.) of the system time base of TS2. In accuracy, PCR of the beginning of TS2 starts STC2 from the time of day inputted into T-STD. It carries out.

[0345] The offset between STC1 and STC2 is determined as follows. end is PTS on PTS1STC1 corresponding to the video presentation unit of the last of TS1, PTS2start is PTS on STC2 corresponding to the video presentation unit of the beginning of TS2, and if Tpp considers as the display period of the video presentation unit of the last of TS1, offset STC\_delta between two system time base will be computed by the degree type.

STC\_delta = PTS1end+Tpp-PTS2start [0346] Explaining the timing of the presentation of an audio may have the overlap of the display timing of an audio presentation unit in a node, and they are 0 thru/or under 2 audio frame (see "audio overlap" currently illustrated in <u>drawing 105</u>). Which audio sample being chosen and carrying out resynchronization of the display of an audio presentation unit to the time base where it was amended after the node are set up by the player side.

[0347] In time of day T5, the audio presentation unit of the last of TS1 is displayed for explaining about the system time clock of DVR-STD. The system time clock may overlap among T5 from time of day T2. In this section, DVR-STD changes a system time clock between the value (STC1) of old time base, and the value (STC2) of new time base. The value of STC2 is computed by the degree type.

STC2=STC1-STC\_delta [0348] The continuity of buffering is explained. STC11 video\_end is the value of STC on the system time base STC 1 in case the cutting tool of the last of the video packet of the last of TS1 arrives to TB1 of DVR-STD. STC22 video\_start is the value of STC on the system time base STC 2 in case the cutting tool of the beginning of the video packet of the beginning of TS2 arrives to TB1 of DVR-STD. STC21 video\_end is STC11

video\_end. It is the value which converted the value into the value on the system time base STC 2. STC21 video\_end is computed by the degree type. STC21 video\_end = STC11 video\_end -STC\_delta [0349] In order to follow DVR-STD, it is required that the following two conditions should be fulfilled. First, the arrival timing to TB1 of the video packet of the beginning of TS2 must fill the inequality shown below. And the inequality shown below must be filled.

STC22 video\_start > STC21 video\_end+ deltaT1 -- this inequality is filled -- as -- Clip1 -- and -- or the partial stream of Clip2 -- re-encoding -- and -- or when it is necessary to re-multiplex, it is carried out if needed [ that ].

[0350] next, the input of the video packet from TS2 which continues at the input of the video packet from TS1, and it on the time-axis of the system time base which converted STC1 and STC2 on the same time-axis -- a video buffer -- overflow -- and don't carry out an underflow.

[0351] The content of the data currently recorded on the record medium, playback information, etc. can be managed appropriately, and it has them, and a user can check the content of the data currently recorded on the record medium appropriately at the time of playback, or it can make it possible to reproduce desired data simple by being based on such syntax, DS, and a regulation.

[0352] In addition, although the gestalt of this operation makes an MPEG 2 transport stream an example and explains it as a multiplexing stream, it can be applied also about the DSS transport stream currently used with DirecTV service (trademark) of not only this but an MPEG 2 program stream, or the U.S.

[0353] Next, the syntax of mark\_entry() and representative\_picture\_entry() explains the processing in the case of performing search playback of a scene shown with the marking point in the case of being a configuration as shown in drawing 81 with reference to the flow chart of drawing 106.

[0354] In step S1, the control section 23 of the record regenerative apparatus 1 first reads EP\_Map ( <u>drawing 70</u> ), STC\_Info ( <u>drawing 52</u> ) and Program\_Info ( <u>drawing 54</u> ) which are the data dace of a DVR transport stream file, and ClipMark ( drawing 78 ) from a record medium 100.

[0355] In step S2, a control section 23 creates the list of thumbnails from the picture referred to by representative\_picture\_entry ( <u>drawing 81</u> ) of ClipMark ( <u>drawing 78</u> ), or ref\_thumbnail\_index, outputs it from the terminal 24 as user interface I/O, and is displayed on the menu screen of GUI. In this case, priority is given to ref\_thumbnail\_index over representative\_picture\_entry when ref\_thumbnail\_index has an effective value.

[0356] In step S3, a user specifies the marking point of a playback start point. This is performed because a user chooses a thumbnail image from the inside on the menu screen displayed as GUI. A control section 23 acquires the marking point matched with the specified thumbnail corresponding to this selection actuation.

[0357] In step S4, a control section 23 acquires STC\_sequence\_id with PTS of mark\_time\_stamp of mark\_entry ( <u>drawing 81</u> ) specified at step S3. [0358] In step S5, a control section 23 acquires the source packet number which the STC time-axis corresponding to STC\_sequence\_id acquired by step S4 starts from STC\_Info ( drawing 52 ).

[0359] In step S6, a control section 23 acquires a source packet number with the nearest entry point (I picture) from PTS of the Paquette number which the STC time-axis acquired at step S5 starts, and the marking point acquired by step S4, before being more nearly time than PTS of a marking point.

[0360] A control section 23 reads the data of a transport stream, and is made to supply them to the AV decoder 27 in step S7 from a source packet number with the entry point acquired at step S6.

[0361] A control section 23 controls the AV decoder 27, and makes a display start in step S8 from the picture of PTS of the marking point acquired by step S4.

[0362] The above actuation is further explained with reference to drawing 107 thru/or 109.

[0363] Now, a DVR transport stream file has the STC time-axis of STC\_sequence\_id=id0, and let the source packet number which the time-axis starts be a thing smaller than the source packet number of the scene start point A as shown in <u>drawing 107</u>. And CM (commercials) shall be inserted in from the source packet number B before C.

[0364] As shown in <u>drawing 108</u>, at this time, each PTS is registered into EP\_Map corresponding to EP\_Map shown in <u>drawing 70</u> as PTS (A), PTS (B), and PTS (C) as PTS\_EP\_start corresponding to A, B, and C which are shown by RSPN\_EP\_start.

[0365] Moreover, as shown in <u>drawing 109</u>, as shown in <u>drawing 109</u>, corresponding to the value of a scene start, CM start and the mark type (<u>drawing 79</u>) 0x92 showing CM end, 0x94, and 0x95, mark\_entry and representative\_picture\_entry are recorded on ClipMark corresponding to ClipMark of drawing 78.

[0366] As Mark\_Time\_stamp of mark\_entry, corresponding to the scene start, CM start, and CM end, PTS (a1), PTS (b0), and PTS (c0) are registered, respectively, and each of each STC\_sequence\_id is set to id0.

[0367] Similarly, as Mark\_Time\_stamp of Representative\_picture\_entry, corresponding to the scene start, CM start, and CM end, PTS (a2), PTS (b0), and PTS (c0) are registered, respectively, and, as for each of them, STC\_sequence\_id is set to id0.

[0368] In PTS(A) < PTS (a1), in step S6, the Paquette number A is acquired, the transport stream which begins from the Paquette number A is supplied to the AV decoder 27 in step S7, and a display is started from the picture of PTS (a1) in step S8.

[0369] Next, with reference to the flow chart of <u>drawing 110</u>, the syntax of mark\_entry and representative\_picture\_entry explains processing of CM skip playback in the case of being a configuration as shown in <u>drawing 81</u> with reference to the flow chart of <u>drawing 110</u>.

[0370] In step S21, a control section 23 reads EP\_map ( <u>drawing 70</u> ), STC\_Info ( <u>drawing 52</u> ), Program\_Info ( <u>drawing 54</u> ), and ClipMark ( <u>drawing 78</u> ) from a record medium 100. In step S22, a user specifies CM skip playback from the terminal 24 as user interface I/O.

[0371] In step S23, a control section 23 acquires PTS of the mark information whose mark type ( <u>drawing 79</u> ) is CM start point (0x94), PTS of the mark information which is a point (0x95) ending [ CM ], and STC\_sequence\_id corresponding to a list ( <u>drawing 81</u> ).

[0372] In step S24, a control section 23 acquires the source packet number

which the STC time-axis corresponding to STC\_sequence\_id of CM start point and an ending point starts from STC\_Info ( <u>drawing 52</u> ).

[0373] A control section 23 carries out reading appearance of the transport stream from a record medium 100, supplies it to the AV decoder 27, and makes decoding start in step S25.

[0374] In step S26, as for a control section 23, a current display image investigates whether it is the image of PTS of CM start point. When a current display image is not an image of PTS of CM start point, it progresses to step S27 and, as for a control section 23, the display of an image is continued. Then, as for processing, return and processing after it are repeatedly performed by step S25.

[0375] In step S26, when judged with a current display image being an image of PTS of CM start point, it progresses to step S28, and a control section 23 controls the AV decoder 27, and stops decoding and a display.

[0376] Next, in step S29, a control section 23 acquires the Paquette number which the STC time-axis corresponding to STC\_sequence\_id of the point ending [ CM ] starts, and before being more nearly time than PTS of the point, it acquires a source packet number with the nearest entry point from the Paquette number and PTS of the point acquired by processing of step S23 ending [ CM ].

[0377] A control section 23 reads the data of a transport stream, and is made to supply them to the AV decoder 27 in step S30 from a source packet number with the entry point acquired by processing of step S29. [0378] A control section 23 controls the AV decoder 27, and makes a display resume from the picture of PTS of the point ending [ CM ] in step S31. [0379] If the above actuation is further explained with reference to Fig. 107 thru/or 109, in the case of this example, CM start point and the point ending [ CM ] exist on a common STC time-axis called STC\_sequence\_id=id0, and let the source packet number which that STC time-axis starts be a thing smaller than the source packet number A of the start point of a scene. [0380] A transport stream is decoded, and a display is suspended by the AV decoder 27 when judged with display time of day having been set to PTS (b0) at step S26 (when judged with it being CM start point). And in PTS(C) <PTS

(c0), at step S30, decoding is resumed from the stream which begins from the data of the Paquette number C, and a display is resumed from the picture of PTS (c0) in step S31.

[0381] In addition, this approach can be applied, not only CM skip playback but when skipping the scene for two points generally specified by ClipMark and reproducing.

[0382] Next, mark\_entry and representative\_picture\_entry explain search regeneration of CM shown with the marking point in the case of being the syntax structure shown in <u>drawing 82</u> with reference to the flow chart of drawing 112.

[0383] In step S41, a control section 23 acquires the information on EP\_map ( <u>drawing 70</u> ), STC\_Info ( <u>drawing 52</u> ), Program\_Info ( <u>drawing 54</u> ), and ClipMark ( drawing 78 ).

[0384] next, a control section 23 generates the list of thumbnails from the picture referred to by representative\_picture\_entry ( <a href="mailto:drawing 82">drawing 82</a>) or ref\_thumbnail\_index contained in ClipMark ( <a href="mailto:drawing 78">drawing 78</a>) which carried out reading appearance at step S41, and is made to display it on the menu screen of GUI in step S42 Priority is given to ref\_thumbnail\_index over representative\_picture\_entry when ref\_thumbnail\_index has an effective value. [0385] In step S43, a user specifies the marking point of a playback start point. This assignment is performed by specifying the marking point in which a user chooses a thumbnail image, is matched with that thumbnail, and is from the inside on the menu screen displayed by processing of step S42. [0386] In step S44, a control section 23 acquires RSPN\_ref\_EP\_start and offset\_num\_pictures ( <a href="mailto:drawing 82">drawing 82</a>) of a marking point which were specified by processing of step S43.

[0387] A control section 23 reads the data of a transport stream from the source packet number corresponding to RSPN\_ref\_EP\_start acquired at step S44, and is made to supply them to the AV decoder 27 in step S45.
[0388] A control section 23 makes a display start from the picture in step S46, when the AV decoder 27 is controlled, the picture which should be displayed (without) is counted up from the picture referred to by RSPN\_ref\_EP\_start and counted value becomes offset\_num\_pictures.

[0389] The above processing is further explained with reference to Fig. 113 thru/or 115. In this example, the scene has started the DVR transport stream file from the source packet number A, and CM is inserted from the source packet number B to the source packet C. For this reason, as shown in drawing 114, corresponding to A, B, and C as RSPN\_EP\_start, PTS (A), PTS (B), and PTS (C) are registered into EP\_map as PTS\_EP\_start.

[0390] Moreover, as shown in drawing 115, mark\_entry and representative\_picture\_entry are registered corresponding to the scene start, CM start, and the mark type of CM end. Corresponding to the scene start, CM start, and CM end, as RSPN\_ref\_EP\_start, A, B, and C are registered into mark\_entry, respectively, and M1, N1, and N2 are registered into it as offset\_num\_pictures. Similarly, as RSPN\_ref\_EP\_start, corresponding to the scene start, CM start, and CM end, A, B, and C are registered into representative\_picture\_entry, respectively, and M2, N1, and N2 are registered into it as offset\_num\_pictures, respectively.

[0391] When it \*\*\*\* from the picture which is in charge of a scene start, and it is ordered in playback, and decoding is started from the stream which begins from the data of the Paquette number A, the picture which should be displayed from the picture of PTS (A) (without it displays) is counted up and offset\_num\_pictures becomes the value of M1, a display is started from the picture.

[0392] Furthermore, the syntax of mark\_entry and representative\_picture\_entry explains processing of CM skip playback in the case of being the configuration shown in <u>drawing 82</u> with reference to the flow chart of drawing 116.

[0393] In step S61, a control section 23 acquires the information on EP\_map ( <u>drawing 70</u> ), STC\_Info ( <u>drawing 52</u> ), Program\_Info ( <u>drawing 54</u> ), and ClipMark ( <u>drawing 78</u> ).

[0394] In step S62, if a user orders it CM skip playback, in step S63, a control section 23 will acquire RSPN\_ref\_EP\_START and offset\_num\_pictures (<a href="mailto:drawing 82">drawing 82</a>) as mark information of each point whose mark types (<a href="mailto:drawing 79">drawing 82</a>) are CM start point and a point ending [ CM ]. And the data of CM start point are made into RSPN\_ref\_EP\_start (1) and offset\_num\_pictures (1), and

the data of the point ending [ CM ] are made into RSPN\_ref\_EP\_start (2) and offset\_num\_pictures (2).

[0395] In step S64, a control section 23 acquires PTS corresponding to RSPN\_ref\_EP\_start (1) and RSPN\_ref\_EP\_start (2) from EP\_map ( <u>drawing</u> 70 ).

[0396] A control section 23 carries out reading appearance of the transport stream from a record medium 100, and is made to supply to the AV decoder 27 in step S65.

[0397] In step S66, a control section 23 judges whether a current display image is the picture of PTS corresponding to RSPN\_ref\_EP\_start (1), when a current display image is not the picture of PTS corresponding to RSPN\_ref\_EP\_start (1), progresses to step S67 and displays a picture continuously as it is. Then, as for processing, return and processing after it are repeatedly performed by step S65.

[0398] In step S66, when it judges that a current display image is the picture of PTS corresponding to RSPN\_ref\_EP\_start (1), it progresses to step S68, and a control section 23 stops a display, when the AV decoder 27 is controlled, the picture displayed from the picture of PTS corresponding to RSPN\_ref\_EP\_start (1) is counted up and counted value becomes offset\_num\_pictures (1).

[0399] A control section 23 reads the data of a transport stream from the source packet number of RSPN\_ref\_EP\_start (2), and is made to supply them to the AV decoder 27 in step S69.

[0400] A control section 23 makes a display start from the picture in step S70, when the AV decoder 27 is controlled, the picture which should be displayed from the picture of PTS corresponding to RSPN\_ref\_EP\_start (2) (without it displays) is counted up and counted value becomes offset\_num\_pictures (2). [0401] If the above actuation is further explained with reference to Fig. 113 thru/or 115, the time of day PTS corresponding to the Paquette numbers B and C (B) and PTS (C) will be first obtained based on EP\_map ( drawing 114 ). And when Clip AV stream is decoded and display time of day is set to PTS (B), a display picture counts up from the picture of PTS (B), and a display is suspended when the value is set to N1 ( drawing 115 ).

[0402] Furthermore, decoding is resumed from the stream which begins from the data of the Paquette number C, and when the picture which should be displayed from the picture of PTS (C) (without it displays) is counted up and the value is set to N2 (<u>drawing 115</u>), a display is resumed from the picture. [0403] The above processing can be applied, not only CM skip playback but when making the scene for two points specified by ClipMark skip and reproducing.

[0404] Next, the syntax of mark\_entry and representative\_picture\_entry explains search regeneration of the scene shown with the marking point in the case of being a configuration as shown in <u>drawing 84</u> with reference to the flow chart of drawing 118.

[0405] The information on ClipMark ( <u>drawing 78</u> ) is acquired by EP\_map ( <u>drawing 70</u> ), STC\_Info ( <u>drawing 52</u> ), Program\_Info ( <u>drawing 54</u> ), and the list in step S81.

[0406] A control section 23 generates the list of thumbnails from the picture referred to by representative\_picture\_entry or ref\_thumbnail\_index of ClipMark ( <u>drawing 78</u> ), and is made to display it as a menu screen of GUI in step S82. Priority is given to ref\_thumbnail\_index over representative\_picture\_entry when ref\_thumbnail\_index has an effective value.

[0407] In step S83, a user specifies the marking point of a playback start point. A user chooses a thumbnail image from the inside for example, on a menu screen, and this assignment is performed by specifying the marking point matched with that thumbnail.

[0408] In step S84, a control section 23 acquires RSPN\_mark\_point ( <u>drawing</u> 84 ) of mark\_entry specified by the user.

[0409] In step S85, a control section 23 is before RSPN\_mark\_point of a marking point, and acquires the nearest source packet number of an entry point from EP\_map ( drawing 70 ).

[0410] A control section 23 reads the data of a transport stream from the source packet number corresponding to the entry point acquired at step S85, and is made to supply them to the AV decoder 27 in step S86.

[0411] A control section 23 controls the AV decoder 27, and makes a display start in step S87 from the picture referred to by RSPN\_mark\_point.

[0412] The above processing is further explained with reference to Fig. 119 thru/or 121. In this example, a DVR transport stream file carries out a scene start by the source packet A, and CM is inserted from the source packet number B to C. For this reason, corresponding to A, B, and C as RSPN\_EP\_start, PTS\_EP\_start is registered into EP\_map of drawing 120 as PTS (A), PTS (B), and PTS (C), respectively. moreover, ClipMark shown in drawing 121 -- a scene start, CM start, and CM -- and -- alike -- corresponding -- as RSPN\_mark\_point of markentry -- a1, b1, and c1 -- moreover, a2, b1, and c1 are registered as RSPN\_mark\_point of representative\_picture\_entry, respectively.

[0413] When \*\*\*\*(ing) and reproducing from the picture which is in charge of a scene start, if Paquette number A<a1, decoding will be started from the stream which begins from the data of the Paquette number A, and a display will be started from the picture corresponding to the source packet number a1. [0414] Next, the syntax of mark\_entry and representative\_picture\_entry explains processing of CM skip playback in the case of being a configuration as shown in drawing 84 with reference to the flow chart of drawing 122 and drawing 123.

[0415] In step S101, a control section 23 acquires the information on ClipMark ( <u>drawing 70</u> ) in EP\_map ( <u>drawing 70</u> ), STC\_Info ( <u>drawing 52</u> ), Program\_Info ( drawing 54 ), and a list.

[0416] In step S102, a user specifies CM skip playback.

[0417] In step S103, a control section 23 acquires RSPN\_mark\_point ( drawing 84 ) of the mark information of each point whose mark types ( drawing 79 ) are CM start point and a point ending [ CM ]. And a control section 23 makes the data of CM start point RSPN\_mark\_point (1), and makes the data of the point ending [ CM ] RSPN\_mark\_point (2).

[0418] A control section 23 carries out reading appearance of the transport stream from a record medium 100, and the AV decoder 27 is made to output and decode it in step S104.

[0419] In step S105, a control section 23 judges whether a current display image is a picture corresponding to RSPN\_mark\_point (1), when a current display image is not a picture corresponding to RSPN\_mark\_point (1),

progresses to step S106 and displays a picture continuously as it is. Then, as for processing, return and processing after it are repeatedly performed by step S104.

[0420] In step S105, when it judges that a current display image is a picture corresponding to RSPN\_mark\_point (1), it progresses to step S107, and a control section 23 controls the AV decoder 27, and stops decoding and a display.

[0421] Next, in step S108, the source packet number which is before RSPN\_mark\_point (2) and has the nearest entry point is acquired from EP\_map ( drawing 70 ).

[0422] A control section 23 reads the data of a transport stream from the source packet number corresponding to the entry point acquired at step S108, and is made to supply them to the AV decoder 27 in step S109.

[0423] A control section 23 controls the AV decoder 27, and makes a display resume in step S110 from the picture referred to by RSPN\_mark\_point (2). [0424] A display is suspended, when the example of Fig. 119 thru/or 121 explained the above processing further, and Clip AV stream is decoded, it goes and it becomes a display picture corresponding to the source packet number b1 ( drawing 121 ). And when it was the source packet number C< source packet number c1, and decoding is resumed and it becomes a picture corresponding to the source packet number c1 from the stream which begins from the data of the Paquette number C, a display is resumed from the picture. [0425] As shown in drawing 124 as mentioned above, on PlayList, a position can be specified with a time stump, this time stump can be changed into a data address in Clip Information of each Clip, and the position of Clip AV stream can be accessed.

[0426] If a user specifies a bookmark and a resume point as a time stump on a time-axis as PlayListMark on PlayList as shown in <u>drawing 125</u>, when reproducing, the PlayList can use ClipMark of Clip which the PlayList is referring to, and, more specifically, can be accessed at the scene start point and the point ending [ scene ] of Clip AV stream.

[0427] In addition, the syntax of ClipMark is changed to the example of drawing 78, and can be shown in drawing 126.

[0428] RSPN\_mark is changed and inserted in reserved\_for\_MakerID, mark\_entry(), and representative\_picture\_entry() of drawing 78 in this example. The 32-bit field of this RSPN\_mark shows the relative address of the source packet which contains the 1st byte of the access unit which that mark refers to on AV stream file. RSPN\_mark is magnitude which makes a source packet number a unit, is defined in Clip Information file from the source packet of the beginning of AV stream file, and counts the value of offset\_SPN as initial value.

[0429] Other configurations are the same as that of the case in <u>drawing 78</u>. [0430] The syntax of ClipMark can also be constituted as further shown in <u>drawing 127</u>. In this example, RSPN\_ref\_EP\_start and offset\_num\_pictures are inserted instead of RSPN\_mark in <u>drawing 126</u>. These are the same as that of the case where it is shown in drawing 82.

[0431] Drawing 128 is a flow chart explaining the creation of ClipMark of syntax shown in drawing 81, when encoding and recording an analog AV signal. It explains referring to the block diagram of the record regenerative apparatus 1 of drawing 1. In step S200, the analysis section 14 analyzes the input AV signal from terminals 11 and 12, and detects the focus. The focus specifies the characteristic scene resulting from the content of the AV stream, for example, is a head broth point, a point changing [ scene ], etc. of a program.

[0432] Step S201 sets and a control section 23 acquires PTS of the image of the focus. In step S202, a control section 23 stores the information on the focus in ClipMark. Specifically, the information explained by the syntax and semantics of ClipMark of this operation is stored. [ of a gestalt ] In step S203, Clip Information file and Clip AV stream file are recorded on a disk. [0433] <a href="Drawing 129">Drawing 129</a> is a flow chart explaining the creation of ClipMark of syntax shown in <a href="drawing 81">drawing 81</a>, when recording the transport stream inputted from the digital interface. It explains referring to the block diagram of the record regenerative apparatus 1 of <a href="drawing 1">drawing 1</a>. In step S211, a demultiplexer 26 and a control section 23 acquire the elementary stream PID of the program to record. When there are two or more elementary streams for analysis, all the elementary streams PID are acquired.

[0434] At step S212, a demultiplexer 26 separates an elementary stream from the program of the transport stream inputted from a terminal 13, and the AV decoder 27 decodes it to AV signal. In step S213, the analysis section 14 analyzes the above-mentioned AV signal, and detects the focus.

[0435] In step S214, a control section 23 acquires PTS of the image of the focus, and STC-sequence-id of STC to which it belongs. At step S215, a control section 23 stores the information on the focus in ClipMark. Specifically, the information explained by the syntax and semantics of ClipMark in the gestalt of this operation is stored.

[0436] In step S216, Clip Information file and Clip AV stream file are recorded on a disk.

[0437] It carries out like the flow chart shown in <u>drawing 128</u>, and the flow chart shown in <u>drawing 129</u>, and ClipMark which stores the mark indicating the characteristic image in AV stream file, i.e., a Clip AV stream file, is recorded, the management information data file, i.e., the Clip Information file, of said AV stream.

[0438] <u>Drawing 130</u> is a flow chart explaining creation of Real PlayList. It explains referring to the block diagram of the record regenerative apparatus 1 of <u>drawing 1</u>. In step S221, a control section 23 records a Clip AV stream. In step S222, a control section 23 creates PlayList() which consists of PlayItem which covers all the refreshable range of Above Clip. An STC break point is in Clip, and when PlayList() consists of two or more PlayItem(s), connection\_condition between PlayItem(s) is also determined.

[0439] In step S223, a control section 23 creates UIAppInfoPlayList(). In step S224, a control section 23 creates PlayListMark. In step S225, a control section 23 creates MakersPrivateData. In step S226, a control section 23 records a Real PlayList file.

[0440] Thus, whenever it records a Clip AV stream newly, one Real PlayList file is made.

[0441] <u>Drawing 131</u> is a flow chart explaining creation of Virtual PlayList. In step S231, it lets a user interface pass and playback of one Real PlayList currently recorded on the disk is specified. And out of the playback range of the Real PlayList, it lets a user interface pass and the playback section shown

with IN point and an OUT point is specified.

[0442] In step S232, a control section 23 judges whether all assignment actuation of the playback range by the user was completed. In step S232, when it is judged that assignment actuation of the playback range by the user is not ended yet, return and processing after it are repeated by step S231, and when it is judged that it ended, it progresses to step S233.

[0443] In step S233, a user is determined through a user interface or the connection condition (connection\_condition) during the two playback sections reproduced continuously is determined by the control section 23. In step S234, it lets a user interface pass and a user specifies subpass (audio for postrecording) information. When a user does not create subpass, the processing in step S234 is skipped.

[0444] In step S235, a control section 23 creates PlayList() based on the playback range information specified by a user, and connection\_condition. In step S236, a control section 23 creates UIAppInfoPlayList(). In step S237, a control section 23 creates PlayListMark. In step S238, a control section 23 creates MakersPrivateData. A control section 23 makes a Virtual PlayList file record on a disk in step S239.

[0445] Thus, the playback section which a user wants to see is chosen from the playback range of Real PlayList currently recorded on the disk, and one Virtual PlayList file is created for every thing which carried out grouping of the playback section.

[0446] <u>Drawing 132</u> is a flow chart explaining playback of PlayList. It explains referring to the block diagram of the record regenerative apparatus 1 of <u>drawing 1</u>. In step S241, a control section 23 acquires the information on Info.dvr, Clip Information file, PlayList file, and a thumbnail file, creates the GUI screen in which the list of PlayList currently recorded on the disk is shown, lets a user interface pass, and displays it on GUI.

[0447] In step S242, it lets a user interface pass and a user directs playback of one PlayList to a control section 23. In step S243, a control section 23 acquires the source packet number which has the nearest entry point in front in time than IN\_time from STC-sequence-id of current PlayItem, and PTS of IN\_time. In step S244, a control section 23 reads the data of AV stream from

a source packet number with the above-mentioned entry point, and supplies them to the AV decoder 27.

[0448] When playback of PlayItem is before in time [ of Above PlayItem ], in step S245, a control section 23 controls to perform connection processing of the display with the PlayItem according to connection\_condition. In step S246, the AV decoder 27 starts a display from the picture of PTS of IN\_time. [0449] In step S247, the AV decoder 27 decodes AV stream continuously. In step S248, as for a control section 23, the image of a current display judges whether it is the image of PTS of OUT\_time. In step S248, the image of a current display progresses to step S250, when it is judged that it is the image of PTS of OUT\_time, and when it is judged that it is not the image of PTS, it progresses to step S249.

[0450] In step S249, processing for displaying the image judged to be the image of PTS is performed, and return and processing after it are repeated by step S247 after that. On the other hand, in step S250, it is judged for current PlayItem by the control section 23 in PlayList whether it is the last PlayItem. In step S250, processing of the flow chart shown in drawing 132 when it was judged that current PlayItem is the last PlayItem in PlayList is ended, and when it is judged that it is not the last PlayItem, return and processing after it are repeated by step S243.

[0451] <u>Drawing 133</u> is a flow chart explaining creation of PlayListMark. It explains referring to the block diagram of the record regenerative apparatus 1 of <u>drawing 1</u>. In step S261, a control section 23 acquires the information on Info.dvr, Clip Information file, PlayList file, and Thumbnail file, creates the GUI screen in which the list of PlayList currently recorded on the disk is shown, lets a user interface pass, and displays it on GUI.

[0452] In step S262, it lets a user interface pass and playback of one PlayList is directed to a control section 23 by the user. In step S263, the playback section 3 starts playback of directed PlayList (carried out as explained with reference to the flow chart of drawing 132).

[0453] In step S264, it lets a user interface pass and the set of a mark is directed to a control section 23 by the user at the place of a favorite scene. In step S265, a control section 23 acquires PTS of a mark, and PlayItem\_id of

PlayItem to which it belongs.

[0454] In step S266, a control section 23 stores the information on a mark in PlayListMark(). In step S267, a PlayList file is recorded on a disk.

[0455] Thus, PlayListMark which stores the mark which shows the Resume point when reproducing the marking point which the user specified out of the playback range of PlayList, or its PlayList is recorded on a PlayList file. [0456] <a href="Drawing 134">Drawing 134</a> is a flow chart explaining the head broth playback for which ClipMark of Clip which PlayListMark and its PlayList refer to was used, when PlayList is reproduced. The syntax of ClipMark() shall be shown in <a href="drawing 81">drawing 81</a>. It explains referring to the block diagram of the record regenerative apparatus 1 of drawing 1.

[0457] In step S271, a control section 23 acquires the information on Info.dvr, Clip Information file, PlayList file, and Thumbnail file, creates the GUI screen in which the list of PlayList currently recorded on the disk is shown, lets a user interface pass, and displays it on GUI.

[0458] In step S272, it lets a user interface pass and playback of one PlayList is directed by the user. In step S273, a control section 23 displays a user interface on GUI through the list of thumbnails generated from the picture referred to by PlayListMark and ClipMark of Clip which the PlayList refers to. [0459] In step S274, it lets a user interface pass and the marking point of a playback start point is specified as a control section 23 by the user. In step S275, a control section 23 judges whether it is the mark to which the mark chosen by the processing in step S274 is stored in PlayListMark. When it is judged that it is the mark which is not progressed and stored in step S276 when the selected mark is judged to be the mark currently stored in PlayListMark in step S275, it progresses to step S278.

[0460] In step S276, a control section 23 acquires PTS of a mark, and PlayItem\_id to which it belongs. In step S277, a control section 23 acquires STC-sequence-id of AV stream which PlayItem which PlayItem\_id points out refers to.

[0461] A control section 23 makes AV stream input into the AV decoder 27 in step S278 based on STC-sequence-id and PTS of a mark. Specifically, step S243 of the flow chart of drawing 132 and the same processing as S244 are

performed using this STC-sequence-id and PTS of a marking point. In step S279, the playback section 3 starts a display from the picture of PTS of a marking point.

[0462] As explained with reference to <u>drawing 9</u>, when PlayList is reproduced, the mark currently stored in ClipMark of Clip which the PlayList refers to can be referred to. Therefore, when Real PlayList and two or more Virtual PlayList are referring one Clip, since those PlayList(s) can share ClipMark of the one Clip, they can manage the data of a mark efficiently.

[0463] Temporarily, when what doubled PlayListMark and ClipMark only with PlayList is defined and Real PlayList and two or more Virtual PlayList are referring one Clip like the above-mentioned example, each PlayList will have the mark information of Clip of the same content, and the effectiveness of record of data is bad, without defining ClipMark as Clip.

[0464] <u>Drawing 135</u> is drawing showing example of another of the syntax of PlayListMark(). length shows the byte count from the cutting tool just behind this length field to the cutting tool of the last of PlayListMark().

number\_of\_PlayList\_marks shows the number of entries of the mark currently stored in PlayListMark.

[0465] mark\_invalid\_flag is a 1-bit flag, and when it is shown that this mark has effective information when the value of this is set to zero and the value of this is set to 1, it is shown that this mark is invalid.

[0466] You may make it the record regenerative apparatus 1 change the value of the mark\_invalid\_flag into 1, when a user does operation which eliminates the entry of one mark on a user interface instead of eliminating the entry of the mark from PlayListMark.

[0467] mark\_type has the semantics which shows the type of a mark and is shown in drawing 136. mark\_name\_length shows the cutting tool length of the mark name shown in the Mark\_name field. The value of this field is 32 or less. ref\_to\_PlayItem\_id shows the value of PlayItem\_id which specifies PlayItem on which the mark is put. The value of PlayItem\_id corresponding to a certain PlayItem is defined in PlayList().

[0468] mark\_time\_stamp stores the time stump in which the point with which the mark was specified is shown. mark\_time\_stamp points out the time

amount in the playback range pinpointed by IN\_time defined in PlayItem shown by ref\_to\_PlayItem\_id, and OUT\_time. The semantics of a time stump is the same as drawing 44.

[0469] When entry\_ES\_PID is set to 0xFFFF, the mark is a pointer to a timeaxis top common to all the elementary streams used by PlayList. When entry\_ES\_PID is set to the value which is not 0xFFFF, entry\_ES\_PID shows the value of PID of transport Paquette containing the elementary stream to which it is pointed out by the mark.

[0470] ref\_thumbnail\_index shows the information on the thumbnail image added to a mark. The semantics is the same as ref\_thumbnail\_index of drawing 42 . mark\_name shows the identifier of a mark. The byte count shown by mark\_name\_length from the left in this field is an effective character alphabetic character, and an identifier is shown. This character alphabetic character is encoded by the approach shown by character\_set in UIAppInfoPlayList.

[0471] As for the value of the cutting tool who follows these effective characters alphabetic character in the mark\_name field, what kind of value may be in close. In the case of this syntax, a mark can point out a specific elementary stream. For example, while PlayList is referring to the multi-view program which has two or more video streams in a program, entry\_ES\_PID is used in order to set the video PID in which one video stream in the program is shown.

[0472] PlayList to which a user refers to a multi-view program is reproduced, and the user presupposes that one view in a multi-view is seen. Suppose that the command was now sent so that a user might skip playback to the following marking point to the record regenerative apparatus 1. In this case, the mark of entry\_ES\_PID which is the same value as the video PID of the view which the user is looking at now should be used for the record regenerative apparatus 1, and, as for the record regenerative apparatus 1, it should not change a view freely. The mark to which entry\_ES\_PID is set to 0xFFFF may be used for the record regenerative apparatus 1 again. In this case, the record regenerative apparatus 1 does not change a view freely. [0473] Drawing 137 is drawing showing example of another of ClipMark() of

syntax shown in <u>drawing 81</u>. length shows the byte count from the cutting tool just behind this length field to the cutting tool of the last of ClipMark(). maker\_ID shows the manufacturer ID of the manufacturer who defines the mark\_type, when mark\_type shows the value of 0x7F from 0x60. [0474] number\_of\_Clip\_marks shows the number of entries of the mark currently stored in ClipMark. mark\_invalid\_flag is a 1-bit flag, and when it is shown that this mark has effective information when the value of this is set to zero and the value of this is set to 1, it is shown that this mark is invalid. [0475] When a user does operation which eliminates the entry of one mark on a user interface, the value of the mark\_invalid\_flag may be made to be changed into 1 instead of a record machine eliminating the entry of the mark from ClipMark. mark\_type has the semantics which shows the type of a mark and is shown in drawing 138.

[0476] ref\_to\_STC\_id shows STC-sequence-id which specifies STC-sequence on which both mark\_time\_stamp and representative\_picture\_time\_stamp are put. The value of STC-sequence-id is defined in STCInfo(). mark\_time\_stamp is the same semantics as mark\_time\_stamp in the case of mark\_entry() of drawing 81.

[0477] When entry\_ES\_PID is set to 0xFFFF, the mark is a pointer to a time-axis top common to all the elementary streams in Clip. When entry\_ES\_PID is set to the value which is not 0xFFFF, entry\_ES\_PID shows the value of PID of transport Paquette containing the elementary stream to which it is pointed out by the mark.

[0478] ref\_to\_thumbnail\_index shows the information on the thumbnail image added to a mark. The semantics is the same as ref\_thumbnail\_index of drawing 78 . representative\_picture\_time\_stamp is the same semantics as mark\_time\_stamp in the case of representative\_picture\_entry() of drawing 81 . [0479] In the case of the syntax shown in drawing 137, a mark can point out a specific elementary stream. For example, when Clip includes the multi-view program which has two or more video streams in a program, entry\_ES\_PID is used in order to set the video PID in which one video stream in the program is shown.

[0480] PlayList to which a user refers to a multi-view program is reproduced,

and the user presupposes that one view in a multi-view is seen. Suppose that the command was now sent so that a user might skip playback to the following marking point to the record regenerative apparatus 1. In this case, the mark of entry\_ES\_PID which is the same value as the video PID of the view which the user is looking at now should be used for the record regenerative apparatus 1, and, as for the record regenerative apparatus 1, it should not change a view freely. The mark to which entry\_ES\_PID is set to 0xFFFF may be used for the record regenerative apparatus 1 again. In this case, the record regenerative apparatus 1 does not change a view freely. [0481] The content of the data currently recorded on the record medium 100, playback information, etc. can be managed appropriately, and it has them, and a user can check the content of the data currently recorded on the record medium appropriately at the time of playback, or it can make it possible to reproduce desired data simple by being based on such syntax, DS, and a regulation.

[0482] According to the database configuration of the gestalt of this operation, by edit etc., since it dissociates independently and a PlayList file and a Clip Information file are recorded, when predetermined PlayList and the content of Clip are changed, it is not necessary to change other files which are unrelated to the file. Therefore, time amount which can change the content of the file easily and the modification and record take can be made small.

[0483] Moreover, only Info.dvr is read first, the content of record of a disk is shown to a user interface, and if only the PlayList file in which the user did playback directions, and the Clip Information file relevant to it are read from a disk, a user's latency time can be made small.

[0484] Temporarily, if all PlayList files and Clip Information files are collectively recorded on one file, the file size will become very large. Therefore, the time amount which it takes in order to change the content of the file and to record it becomes very large compared with the case where dissociate independently and each file is recorded. By applying this invention, it becomes possible to prevent such a thing.

[0485] As mentioned above, ClipMark which stores the mark indicating the characteristic image in AV stream file, i.e., a Clip AV stream file It records, the

management information data file, i.e., the Clip Information file, of said AV stream. Moreover, an object with the information on one playback procedure defined with the combination of the section when it was specified in AV stream, That is, PlayListMark which stores the mark which shows the Resume point when reproducing the marking point specified by a user or its object out of the playback range of PlayList is recorded on an object.

[0486] When PlayList is reproduced by doing in this way, the mark currently stored in ClipMark of Clip which the PlayList refers to can be referred to. Therefore, when Real PlayList and two or more Virtual PlayList are referring one Clip, since those PlayList(s) can share ClipMark of the one Clip, they can manage the data of a mark efficiently.

[0487] Temporarily, when what doubled PlayListMark and ClipMark only with PlayList is defined and Real PlayList and two or more Virtual PlayList are referring one Clip like the above-mentioned example, each PlayList will have the mark information of Clip of the same content, and the effectiveness of record of data is bad, without defining ClipMark as Clip. By applying this invention, it becomes possible to prevent such a thing.

[0488] As mentioned above, it is possible by file-izing ClipMark for storing EP\_map for storing the address of an entry point, the type (for example, point of a program pulling out the head) of the picture of a marking point, and the address in AV stream of the picture as attached information on AV stream as Clip Information File, and recording it on a record medium 100 to manage appropriately the encoded information of a stream required for playback of a stream required for playback of AV stream.

[0489] Using this Clip Information file information, a user can search the scene which is interested out of AV stream currently recorded on the record medium 100, for example, the point of a program pulling out the head etc., and the decision of the read-out location of AV stream from a record medium 100 becomes easy to a user's random access or directions of special playback, and decode initiation of a stream can be performed promptly. [0490] Although a series of processings mentioned above can also be performed by hardware, they can also be performed with software. The record regenerative apparatus 1 is constituted by the personal computer as shown in

drawing 139 in this case.

[0491] In drawing 139, CPU (Central Processing Unit)201 performs various kinds of processings according to the program memorized by ROM (Read Only Memory)202 or the program loaded to RAM (Random Access Memory)203 from the storage section 208. To RAM203, CPU201 performs various kinds of processings upwards again, and required data etc. are memorized suitably.

[0492] CPU201, ROM202, and RAM203 are mutually connected through the bus 204. The input/output interface 205 is also connected to this bus 204 again.

[0493] The communications department 209 which consists of the storage section 208 which consists of a display which consists of the input section 206 which consists of a keyboard, a mouse, etc., CRT, LCD, etc., the output section 207 which becomes a list from a loudspeaker etc., a hard disk, etc., a modem, a terminal adopter, etc. is connected to the input/output interface 205. The communications department 209 performs the communications processing through a network.

[0494] Drive 210 is connected to an input/output interface 205 again if needed, it is suitably equipped with a magnetic disk 221, an optical disk 222, a magneto-optic disk 223, or semiconductor memory 224, and the computer program by which reading appearance was carried out from them is installed in the storage section 208 if needed.

[0495] Although a series of processings mentioned above can also be performed by hardware, they can also be performed with software. When performing a series of processings with software, the program which constitutes the software is installed in a general-purpose personal computer etc. from a record medium possible [ performing various kinds of functions ] by installing the computer built into the hardware of dedication, or various kinds of programs.

[0496] As shown in <u>drawing 139</u>, this record medium is distributed apart from a computer in order to provide a user with a program. The magnetic disk 221 (a floppy disk is included) with which the program is recorded, an optical disk 222 (CD-ROM (Compact Disk-Read Only Memory) --) DVD (Digital Versatile

Disk) is included. It is not only constituted by the package media which consist of a magneto-optic disk 223 (MD (Mini-Disk) is included) or semiconductor memory 224, but It consists of hard disks with which ROM202 with which a user is provided in the condition of having been beforehand included in the computer, and the program is remembered to be, and the storage section 208 are contained.

[0497] In addition, in this description, even if the processing serially performed according to the sequence that the step which describes the program offered by the medium was indicated is not of course necessarily processed serially, it is a juxtaposition thing also including the processing performed according to an individual.

[0498] Moreover, in this description, a system expresses the whole equipment constituted by two or more equipments.

[0499]

[Effect of the Invention] It sets to a program like the above at the 1st information processor of this invention and an approach, and a list. While generating ClipMark which consists of marks indicating the characteristic image extracted from inputted AV stream as management information for managing AV stream Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream Since PlayListMark which consists of marks indicating the image specified as arbitration was generated, and a user uses ClipMark and PlayListMark as the table which became independent respectively and recorded them on the record medium It becomes possible to access the location of a request of AV stream promptly and certainly.

[0500] In the 2nd information processor of this invention and an approach, and a list, moreover, a program The management information for managing AV stream containing ClipMark which consists of marks indicating the characteristic image extracted from AV stream, Out of the playback section corresponding to PlayList which defines the combination of the predetermined section in AV stream PlayListMark which consists of marks indicating the image which the user specified as arbitration is read. The management information by which reading appearance was carried out, and the information

by PlayLisMark are shown. Since AV stream was reproduced from the location corresponding to ClipMark including ClipMark referred to from the shown information with reference to ClipMark corresponding to PlayList the user instructed playback to be It becomes possible to access the location of a request of AV stream promptly and certainly.

## **DESCRIPTION OF DRAWINGS**

[Brief Description of the Drawings]

[Drawing 1] It is drawing showing the configuration of the gestalt of 1 operation of the record regenerative apparatus which applied this invention.

[Drawing 2] It is drawing explaining a format of the data recorded on a record medium with the record regenerative apparatus 1.

[Drawing 3] It is drawing explaining Real PlayList and Virtual PlayList.

[Drawing 4] It is drawing explaining creation of Real PlayList.

[Drawing 5] It is drawing explaining deletion of Real PlayList.

[Drawing 6] It is drawing explaining assemble editing.

[Drawing 7] It is drawing explaining the case where subpass is prepared in Virtual PlayList.

[Drawing 8] It is drawing explaining modification of the playback sequence of PlayList.

[Drawing 9] It is drawing explaining the mark on PlayList, and the mark on Clip.

[Drawing 10] It is drawing explaining a menu thumbnail.

[Drawing 11] It is drawing explaining the mark added to PlayList.

[Drawing 12] It is drawing explaining the mark added to a clip.

[Drawing 13] It is drawing explaining the relation of PlayList, Clip, and a thumbnail file.

[Drawing 14] It is drawing explaining directory structure.

[Drawing 15] It is drawing showing the syntax of info.dvr.

[Drawing 16] It is drawing showing the syntax of DVR volume.

- [Drawing 17] It is drawing showing the syntax of Resumevolume.
- [Drawing 18] It is drawing showing the syntax of UIAppInfovolume.
- [Drawing 19] It is drawing showing the table of Character set value.
- [Drawing 20] It is drawing showing the syntax of TableOfPlayList.
- [Drawing 21] It is drawing showing other syntax of TableOfPlayList.
- [Drawing 22] It is drawing showing the syntax of MakersPrivateData.
- [Drawing 23] It is drawing showing the syntax of xxxxx.rpls and yyyyy.vpls.
- [Drawing 24] It is drawing explaining PlayList.
- [Drawing 25] It is drawing showing the syntax of PlayList.
- [Drawing 26] It is drawing showing the table of PlayList\_type.
- [Drawing 27] It is drawing showing the syntax of UIAppinfoPlayList.
- [Drawing 28] It is drawing explaining the flag in the syntax of
- UIAppinfoPlayList shown in drawing 27.
- [Drawing 29] It is drawing explaining PlayItem.
- [Drawing 30] It is drawing explaining PlayItem.
- [Drawing 31] It is drawing explaining PlayItem.
- [Drawing 32] It is drawing showing the syntax of PlayItem.
- [Drawing 33] It is drawing explaining IN\_time.
- [Drawing 34] It is drawing explaining OUT\_time.
- [Drawing 35] It is drawing showing the table of Connection\_Condition.
- [Drawing 36] It is drawing explaining Connection\_Condition.
- [Drawing 37] It is drawing explaining BridgeSequenceInfo.
- [Drawing 38] It is drawing showing the syntax of BridgeSequenceInfo.
- [Drawing 39] It is drawing explaining SubPlayItem.
- [Drawing 40] It is drawing showing the syntax of SubPlayItem.
- [Drawing 41] It is drawing showing the table of SubPath\_type.
- [Drawing 42] It is drawing showing the syntax of PlayListMark.
- [Drawing 43] It is drawing showing the table of Mark\_type.
- [Drawing 44] It is drawing explaining Mark\_time\_stamp.
- [Drawing 45] It is drawing showing the syntax of zzzzz.clip.
- [Drawing 46] It is drawing showing the syntax of ClipInfo.
- [Drawing 47] It is drawing showing the table of Clip\_stream\_type.
- [Drawing 48] It is drawing explaining offset\_SPN.

- [Drawing 49] It is drawing explaining offset\_SPN.
- [Drawing 50] It is drawing explaining the STC section.
- [Drawing 51] It is drawing explaining STC\_Info.
- [Drawing 52] It is drawing showing the syntax of STC\_Info.
- [Drawing 53] It is drawing explaining ProgramInfo.
- [Drawing 54] It is drawing showing the syntax of ProgramInfo.
- [Drawing 55] It is drawing showing the syntax of VideoCondingInfo.
- [Drawing 56] It is drawing showing the table of Video\_format.
- [Drawing 57] It is drawing showing the table of frame\_rate.
- [Drawing 58] It is drawing showing the table of display\_aspect\_ratio.
- [Drawing 59] It is drawing showing the syntax of AudioCondingInfo.
- [Drawing 60] It is drawing showing the table of audio\_coding.
- [Drawing 61] It is drawing showing the table of audio\_component\_type.
- [Drawing 62] It is drawing showing the table of sampling\_frequency.
- [Drawing 63] It is drawing explaining CPI.
- [Drawing 64] It is drawing explaining CPI.
- [Drawing 65] It is drawing showing the syntax of CPI.
- [Drawing 66] It is drawing showing the table of CPI\_type.
- [Drawing 67] It is drawing explaining video EP\_map.
- [Drawing 68] It is drawing explaining EP\_map.
- [Drawing 69] It is drawing explaining EP\_map.
- [Drawing 70] It is drawing showing the syntax of EP\_map.
- [Drawing 71] It is drawing showing the table of EP\_type values.
- [Drawing 72] It is drawing showing the syntax of
- EP\_map\_for\_one\_stream\_PID.
- [Drawing 73] It is drawing explaining TU\_map.
- [Drawing 74] It is drawing showing the syntax of TU\_map.
- [Drawing 75] It is drawing showing the syntax of ClipMark.
- [Drawing 76] It is drawing showing the table of mark\_type.
- [Drawing 77] It is drawing showing the table of mark\_type\_stamp.
- [Drawing 78] It is drawing showing other examples of the syntax of ClipMark.
- [Drawing 79] It is drawing showing other examples of the table of Mark\_type.
- [Drawing 80] It is drawing showing the example of mark\_entry() and

representative\_picture\_entry().

[Drawing 81] It is drawing showing the syntax of mark\_entry() and representative\_picture\_entry().

[Drawing 82] It is drawing showing other examples of the syntax of mark\_entry() and representative\_picture\_entry().

[Drawing 83] It is drawing explaining the relation between RSPN\_ref\_EP\_start and offset\_num\_pictures.

[Drawing 84] It is drawing showing other examples of the syntax of mark\_entry() and representative\_picture\_entry().

[Drawing 85] It is drawing explaining the relation between ClipMark and EP\_map.

[Drawing 86] It is drawing showing the syntax of menu.thmb and mark.thmb.

[Drawing 87] It is drawing showing the syntax of Thumbnail.

[Drawing 88] It is drawing showing the table of thumbnail\_picture\_format.

[Drawing 89] It is drawing explaining tn\_block.

[Drawing 90] It is drawing explaining the structure of the transport stream of DVR MPEG 2.

[Drawing 91] It is drawing showing the recorder model of the transport stream of DVR MPEG 2.

[Drawing 92] It is drawing showing the player model of the transport stream of DVR MPEG 2.

[Drawing 93] It is drawing showing the syntax of source packet.

[Drawing 94] It is drawing showing the syntax of TP\_extra\_header.

[Drawing 95] It is drawing showing the table of copy permission indicator.

[Drawing 96] It is drawing explaining seamless connection.

[Drawing 97] It is drawing explaining seamless connection.

[Drawing 98] It is drawing explaining seamless connection.

[Drawing 99] It is drawing explaining seamless connection.

[Drawing 100] It is drawing explaining seamless connection.

[Drawing 101] It is drawing explaining the overlap of an audio.

[Drawing 102] It is drawing explaining the seamless connection using BridgeSequence.

[Drawing 103] It is drawing explaining the seamless connection which does

not use BridgeSequence.

[Drawing 104] It is drawing showing a DVR STD model.

[Drawing 105] It is drawing showing the timing chart of decode and a display.

[Drawing 106] It is a flow chart explaining the search playback of a scene shown with the marking point in the case of the syntax of drawing 81.

[Drawing 107] It is drawing explaining actuation of the playback in the case of the syntax of drawing 81.

[Drawing 108] It is drawing showing the example of EP\_map.

[Drawing 109] It is drawing showing the example of ClipMark.

[Drawing 110] It is a flow chart explaining CM skip regeneration in the case of the syntax of drawing 81.

[Drawing 111] It is a flow chart explaining CM skip regeneration in the case of the syntax of drawing 81.

[Drawing 112] It is a flow chart explaining the search playback of a scene shown with the marking point in the case of the syntax of drawing 82.

[Drawing 113] It is drawing explaining the playback in the case of the syntax of drawing 82.

[Drawing 114] It is drawing showing the example of EP\_map.

[Drawing 115] It is drawing showing the example of ClipMark.

[Drawing 116] It is a flow chart explaining CM skip playback in the case of the syntax of drawing 82.

[Drawing 117] It is a flow chart explaining CM skip playback in the case of the syntax of drawing 82.

[Drawing 118] It is a flow chart explaining the search playback of a scene shown with the marking point in the case of the syntax of drawing 84.

[Drawing 119] It is drawing explaining the playback in the case of the syntax of drawing 84.

[Drawing 120] It is drawing showing the example of EP\_map.

[Drawing 121] It is drawing showing the example of ClipMark.

[Drawing 122] It is a flow chart explaining CM skip playback in the case of the syntax of drawing 84.

[Drawing 123] It is a flow chart explaining CM skip playback in the case of the syntax of drawing 84.

[Drawing 124] It is drawing showing an application format.

[Drawing 125] It is drawing explaining the mark on PlayList, and the mark on Clip.

[Drawing 126] It is drawing showing other examples of the syntax of ClipMark.

[Drawing 127] It is drawing showing the example of further others of the syntax of ClipMark.

[Drawing 128] It is a flow chart explaining creation of ClipMark in the case of encoding and recording an analog AV signal.

[Drawing 129] It is a flow chart explaining creation of ClipMark in the case of recording a transport stream.

[Drawing 130] It is a flow chart explaining creation of RealPlayList.

[Drawing 131] It is a flow chart explaining creation of VirtualPlayList.

[Drawing 132] It is a flow chart explaining playback of PlayList.

[Drawing 133] It is a flow chart explaining creation of PlayListMark.

[Drawing 134] It is a flow chart explaining the search playback at the time of reproducing PlayList.

[Drawing 135] It is drawing showing the syntax of PlayListMark.

[Drawing 136] It is drawing for explaining Mark\_type of PlayListMark.

[Drawing 137] It is drawing showing other syntax of ClipMark.

[Drawing 138] It is drawing for explaining Mark\_type of ClipMark.

[Drawing 139] It is drawing explaining a medium.
